ROGERS PASS ENVIRONMENTAL
ASSESSMENT PANEL

In the matter of Public Meetings of the
Environmental Assessment Panel on CP
Rail's proposed new track development
in Rogers Pass.

PANEL MEMBERS:

P.J. Paradine -- Chairman
Dr. W. Ross
Mr. G. Tench

Held in the Sandman Inn, The Petroleum Room,
Calgary, Alberta, on Friday, the 10th day of
June, 1983, at the hour of 2:00 p.m., Local
Time.

ANGUS, STONEHOUSE & CO. LTD.
TORONTO -- OTTAWA -- WINNIPEG

TABLE OF CONTENTS

AFTERNOON SESSION

PAGE NO.

INTRODUCTORY REMARKS by The Chairman	1
SUBMISSIONS BY:	
Mr. Geof Buck	4
Mr. John Krahn	14
Mr. Geof Buck	23
Mr. John Fox	28
Dr. Kenneth M. Adam	42
Mr. Larry E. Hurwitz	51
Mr. C.R. MacDonald	54
Dr. Bruce Leeson	66

1 ---Upon Commencing at 2:00 p.m.

2 THE CHAIRMAN (Phil Paradine): Good
3 afternoon, ladies and gentlemen. Welcome to the
4 Roughheed Room.

5 As you can see, as we travel along
6 with these meetings we are getting a little closer
7 as time goes on.

8 I am Phil Paradine, for those of you
9 who have not been following the sessions around.
10 I am Chairman of the Environmental Assessment Panel
11 established to consider the environmental and
12 social impacts of C.P. Rail's proposal in Rogers
13 Pass. The other members of the Panel are on my
14 left: Bill Ross and George Tench.

15 These are the final set of meetings
16 and the intent is to advise the Minister of
17 Environment at these meetings on the way in which
18 the project may proceed in an environmentally sound
19 manner. This is being done in accordance with the
20 terms of reference provided by the Minister, a copy
21 of which is in the preliminary report issued by
22 the Panel last year.

23 This report of last year that we
24 made did recommend certain works that could be under-
25 taken by C.P. Rail, and the additional information
26 that was requested, the additional information has
27 been provided to the Panel in April of this year
28 and was sent out for public review. We are now at
29 the stage of holding the public meetings and receiving
30

1 comments on this proposal. The project has been
2 approved in principle by CTC and our mandate is to
3 determine the way in which this may proceed and
4 minimize the impact on the environment.

5 Those of you who want a copy of the
6 report, please leave your name at the back of the
7 room.

8 Procedures, there are copies of the
9 procedures available at the back of the room as
10 well, and if there is any questions, please ask one
11 of the Panel secretariats to assist you.

12 We are making transcripts of the
13 meetings, so if you are speaking, please identify
14 yourself using the microphone. Those that are
15 making presentations, use the microphones over here;
16 and in addition, we have a microphone on the floor
17 for any questions.

18 The schedule is that C.P. Rail will
19 be making a presentation on the topic of the day,
20 which concerns the right-of-way, and I believe they
21 have a number of speakers, following which we
22 will be having a number of technical experts who
23 have been hired by the Panel to give their
24 independent appraisal of this particular proposal,
25 and then I think we will be able to open it up to
26 some questions of the various parties.

27 So, without further to do, I will
28 let Mr. Fox introduce the members of his team and
29 begin his presentation.
30

1 (Fox)

2 MR. JOHN FOX (C.P. Rail): Thank you
3 very much, Mr. Chairman. Ladies and gentlemen,
4 good afternoon.

5 To conserve time, I am not going
6 to introduce the army I have got with me, but I
7 will say this, that we will have basically four
8 presentations, two of which will be done by Geof
9 Buck on geotechnical aspects of the project and
10 the hydrology and debris flow, and John Krahn will
11 do the analysis of the landslide stability and I
12 will somehow get through the design end of it at
13 the end.

14 So, without further ado, I would
15 like Mr. Buck to take over. He will be sitting
16 on the far table at station 7 because he has got
17 some slides.

1 (Buck)

2 MR. GEOFF BUCK (Thurber Consultants):
3 Thank you, Mr. Fox. I am going to present basically
4 a show and tell presentation with slides, describe
5 the geotechnical investigation that was required
6 by C.P. Rail for their assessment and design of
7 earth works, as well as associated structures for
8 their second mainline through Rogers Pass.

9 The investigation is for the route
10 in the Beaver Valley from Rogers Station to the
11 east part of the main tunnel. I will describe the
12 investigation, but not the conceptual designs other
13 than to give a hint of that utilization.

14 So, if I could have the first slide,
15 please. Can you see it or can we have another
16 light off?

17 I might just say that the
18 investigation went from the general to a specific.
19 We started with the geology, surficial geology
20 and bedrock geology through to foundation
21 investigations with drilling equipment and mapping
22 of exposures, both soil and rock and then the
23 assessment of that data and preparation for
24 recommendations.

25 The physical setting, then, is the
26 Beaver Valley. This is the Beaver Valley looking
27 across at the mountain slopes. The mountains in
28 this area rise to 11,500 feet. In the glaciation,
29 which ended approximately -- the major glaciation,
30

1 (Buck)

2 the valley glaciation, which ended about 9,000 years
3 ago before present, this valley here was filled to
4 an elevation of approximately 9,000 feet, filled
5 with ice. Moraines were deposited on these slopes
6 up to a considerable height. That is dense
7 glacial tills.

8 As the ice wasted, it allowed
9 secondary deposits, and moraines to be deposited on
10 the margins of the ice that occupied the center
11 of the valley. They drape down over the glacial
12 tills. As the valley ice melted and there was then
13 a glacial lake within the valley, material eroded
14 out of these, side tributaries were deposited and
15 there were great depths of sand and silt deposited
16 which is now the Beaver River flood plain.

17 There was one interesting event
18 specific to this area about 7500 years ago when
19 ice advanced down the Cupola Creek Valley from the
20 higher level, blocked this drainage and formed a
21 glacial lake to approximately this elevation and
22 allowed elevated deltas from the tributary streams
23 to be deposited at Mountain Creek and Surprise Creek
24 and also in the Beaver River near the east portal
25 of the main tunnel.

26 Subsequent to that, then the ice
27 at Cupola was breached, the valley drained again
28 and then we have the more modern events of primarily
29 material being either washed out of the tributary
30

1 (Buck)

2 streams. These tributary streams then cut down
3 and left elevated terraces again at Alder Creek,
4 Mountain Creek, so that at Mountain Creek, for
5 instance, you have a terrace which is 8400 feet
6 above the existing river. You have a more recent
7 terrace which is maybe 50 below the existing river,
8 and then finally the inside flood plain.

9 In addition, there are debris cones
10 that have been built up at several of those streams,
11 principally Cedar, Raspberry and Surprise Creeks
12 as a result of debris flows down the valleys.

13 This is an exposure of the very
14 competent and dense glacial till that is deposited
15 along the route. This is a view of the access road
16 cut.

17 Here we are looking along the
18 alignment. The aircraft is virtually over the east
19 portal and we are looking down line. The cut in the
20 foreground is made for the Trans Canada Highway
21 construction, and this is the glacial outwash that
22 was deposited in that later glacial lake that I
23 mentioned.

24 Here we have an elevated terrace
25 adjacent to Alder Creek. The creek has subsequently
26 cut down through this again and left a granular
27 deposit, which will be traversed by construction.

28 Here is an example of the debris
29 cone. It is not too distinct, but the modern stream
30

(Buck)

1 has incised to the deep till slopes and eroded
2 and also through debris depositing a very bouldery
3 material in this area here.

4 The terrain, then, defined by the
5 geology, was broken into land forms and in fact
6 the route, and it is approximately ten miles, will
7 cross 39 different land forms. For example, at
8 this location we have the bedrock above the glaciation
9 and then glacial till on these slopes. The
10 fluvial outwash here, which I had showed, and other
11 features along the route. In each of these land
12 forms, the soil has a more or less consistent and
13 distinct soil type.

14 So with that background, I might
15 mention for the bedrock, the bedrock is a metamorphic
16 material. The grade increases generally to the
17 east along this route and the rocks grade from a
18 low grade mica schist up to massive quartzite
19 units.

20 So with that, we then became more
21 specific and addressed the purpose of the
22 investigation, which was the design input, and the
23 design input was to earth works, both the cuts
24 and fills, to define the borrow sources. Well, the
25 borrow, by definition of Parks, must come from the
26 right-of-way cuts and fills. So it is really a
27 question of defining that material which is common
28 borrow, what is usable as filter and what are the
29 sources of rock that would be suitable for rip rap.
30

(Buck)

1 Also for drainage, defining the
2 surficial drainage, but more particularly, ground
3 water because on these non-plastic soils stability
4 is very much related to ground water. Earth
5 retaining structures, then. The parameters were
6 obtained for a variety of earth retaining
7 structures and also for bridges, of course the
8 header slopes and footings are up here, foundation
9 options.

10 For this investigation there was
11 quite a large undertaking and four different drill
12 rigs were used. Becker diesel hammer percussion
13 drill was selected as the main tool because it
14 could penetrate the very coarse and bouldery soils
15 that are found along the route. Samples were obtained
16 by standard penetration tests and becker density
17 tests were also done for assessing the soil density
18 and the ability to drive piles. An air trac
19 pneumatic percussion rig was used basically to
20 profile bedrock. A mud rotary drill was used where
21 necessary to sample sensitive or fine soils,
22 particularly in the flood plain at the east end of
23 the route.

24 Test pits were dug to allow full
25 gradation of the soil to be assessed, as well as
26 to be able to measure the insitu density of the
27 soils with a nuclear densometer.

28 The results of these investigations
29 were compiled in a method which is a new
30

1 (Buck)

2 development, which has been bought and improved and
3 work integrated by C.P. Rail into their design
4 process. This log is a test hole log where in the
5 field information, soils information and the
6 laboratory information is compiled to give a
7 composite picture of the soils at a particular drill
8 hole. This log, the information in the field was
9 compiled on computer input sheets and the data was
10 manipulated by computer and plotted with a pen plotter.

11 Similarly, this information was
12 then transferred onto the topographic sheets.
13 The soil along the route was then -- we had excellent
14 exposures because to allow the drill rigs to get
15 in, an access road had to be built along right-of-way,
16 so we were able to measure the angle of these slopes,
17 and map the soil types, look for bedding, look for
18 bedrock such as here, identify seepage zones and
19 generally just getting a lot of information.

20 On the slopes, it is interesting.
21 The till slopes were typically 41, 42 degrees;
22 the back slopes are in the range of 45 through to
23 60 degrees, and we have had really very little
24 sluffing through this past winter.

25 The ground water was then investigated.
26 The seepage observations have been obtained here.
27 Water zones noted during drilling as well as the
28 results of piezometer readings were compiled and
29 estimates were made of the permeability and the
30

1 (Buck)

2 hydrologic gradient might be anticipated in the
3 slopes. Ground water is -- I am sorry, I might just
4 mention here that the slope information can then
5 be measured on these temporary slopes, could be
6 compiled slope height versus slope angle to indicate
7 what sort of slopes could be used in the temporary
8 excavations for construction, you know, if they are
9 very high, in the order of 50 to 60 degrees. In
10 other words, below this line which is considered
11 a safe line for temporary work.

12 Here we have in the hydrology
13 investigation, you notice that there are damp zones
14 where seepage is coming out and drier zones. Some
15 areas are completely dry. The water is perculating
16 straight down into a very permeable soil. At other
17 locations such as this there are silt stringers in
18 the soil and so the water is tending to day light
19 and has to be considered in design.

20 The soils were then taken and
21 assessed in the laboratory, simple tests like moisture
22 content, identification, grain size, and this shows
23 a compilation of the major soil types, both the
24 outwash and terrace gravels and the moraines
25 They are both well-graded, non-plastic gravelly-
26 silty sands so they are excellent borrow material,
27 very stable, and they are really very erosion-
28 resistent, which is an important environmental
29 consideration.
30

1 (Buck)

2 The soils, as I mentioned, are strong
3 and the strength is basically governed by the
4 matrix material, so we were able to take the fine
5 gravel through to silt fraction and do laboratory
6 tests, track some laboratory tests, and we find here
7 that the strengths were everywhere greater than 38
8 degrees in terms of effective angle of friction
9 and they varied from 38 degrees through to 46 degrees,
10 47 degrees for varying confining pressures with
11 the strength or at least the friction angle increasing
12 with decreasing confining pressures, so dealing
13 with really a very complex material.

14 Again, we were able to take
15 representative samples and do compaction tests which
16 shows that the density is about 131, I guess, to 140
17 optimum at moisture contents of about eight percent.
18 This is a fairly critical point because the
19 ability to compact is very closely related to the
20 moisture content of the soil. The soil in the field
21 on an average is found to be one percent below the
22 optimum moisture content or in other words, you can
23 allow the material to gain some moisture and still
24 you can get good compaction, so this material will
25 compact well.

26 I would like to go on to a description
27 of the bedrock again. As I mention, this is
28 metamorphic rock, and the rock purpose, of course,
29 is to arrive at the safe angle for cut slopes as well
30

1 (Buck)

2 as foundations for bridges and other structures
3 and the ability to retain tie back anchors.

4 The metamorphic rock it is -- there is two aspects
5 to the rock, the fabric or the discontinuities within
6 the rock and the strength or the hardness of the rock
7 itself.

8 Here we have a quartzite deposit, a
9 fairly massive material, a strong or at least hard
10 material, and we have the vertical lineaments which
11 are the schistosity or primary cleavage resulting from
12 metamorphism. In addition, of course, these rocks
13 will have joints at the variety of inclinations.
14 So, we systematically went along to all exposures
15 and mapped this fabric data, recording the dip
16 directions, spacing of joints, type of fill and
17 the continuity of these features.

18 Just very briefly to illustrate
19 how this information can be used, joints in any one
20 direction on this polar stereo-plot will plot in
21 this certain area on the plot here. For instance,
22 if this then is the schistosity and these are
23 cross and down slope joints, they plot in this area
24 and this area, this allows -- and on top of this
25 diagram you then superimpose the orientation of a
26 proposed cut and further, the slope angle of a
27 proposed cut, you can determine whether the joints
28 are likely to cause slippage on a cut slope. This
29 will allow you, then, to either adjust the cut slope
30

1 (Buck)

2 to a flatter angle or to design both in rather
3 permanent support measures.

4 One important aspect here is
5 toppling. In other words, vertically jointed rock
6 with time will tend to tilt and this is a feature.
7 For instance, here we see vertically jointed rock.
8 I am sure it is not very good, but the joints are now
9 over at this angle. In other words, over the
10 centuries, this upper rock with freezing, thawing,
11 et cetera has gradually moved over, so that the
12 design parameters for this mass of rock which has
13 toppled somewhat will be different from the
14 vertically jointed rock, and this has been taken into
15 account into the design recommendations.

16 The rock, therefore -- the strength,
17 it varies from massive quartzite, very competent,
18 down to this mica schist which is relatively weak
19 rock and susceptible to weather. That does not
20 mean it is not competent but it may be weaker rock.

21 So we have investigated a variety
22 of materials, and this information was then
23 compiled and recommendations prepared for construction
24 of retaining walls, such as this reinforced earth
25 wall at the east portal and four bridges, in this
26 case the design parameters for the foundations on
27 sloping approach fills for application to the
28 permanent structures which will replace the structures
29 such as this.
30

1 (Krahn)

2 Thank you.

3 MR. FOX: Do you want to have
4 questions now?

5 THE CHAIRMAN: No, I was going to
6 go right on. I just was wondering whether there
7 was a slide presentation for the next person.

8 MR. FOX: Yes, there is.

9 THE CHAIRMAN: So we will go back
10 to where we were before.

11 MR. JOHN KRAHN (EBA Consultants):
12 Panel members, ladies and gentlemen, I am going to
13 be talking about the landslide and stability
14 considerations along the route.

15 Just a few notes about the
16 presentation. This is a very general presentation.
17 Details of everything that has been done are
18 available in reports. Also, these slides are
19 illustrative. They are not to scale and so they
20 are intended primarily to illustrate features, not
21 to present detail.

22 There are three slide areas along
23 the route: Griffith, the most well-known of these;
24 the unnamed; and the wet area.

25 The Griffith and unnamed are beside
26 each other between Mountain and Cedar Creeks, and
27 this slide simply shows the relationship of the
28 slides relative to the existing line and the new
29 line and the Trans Canada Highway.
30

1 (Krahn)

2 The slide masses or the slide
3 areas are very large. The distance from here to
4 here is approximately 45 hundred feet, and there is
5 a substantial difference in elevation from the
6 flood plain up to the top. The unnamed slide is
7 slightly smaller in length and slightly lower in
8 difference from the flood plain up to the top.

9 The important part about this is
10 the active lobe of the Griffith slide. There is
11 no evidence to indicate that any of this is unstable,
12 but there is some indication that there is a slight
13 amount of movement, and this small area here, which
14 just touches the existing line and the new line
15 will cross the bottom of that.

16 Geological studies indicate by
17 Thurber Consultants that this Griffith slide is a
18 very old slide. There is some landslide debris
19 with some glacial moraine materials overlying the
20 landslide debris, and it is likely that this
21 landslide probably occurred during and inter-glacial
22 period, indicating that it has been there for an
23 awful long time.

24 There is also what appears to be
25 some more recent surficial landslide debris and
26 it appears that this surface material here is what
27 is presently moving.

28 The seepage conditions and ground
29 water conditions are rather well defined by the
30

1 (Krahn)

2 drilling that was done along the new route and some
3 drilling that was done in this area in 1979. There
4 is no well defined water table in the area. There
5 was a little bit of seepage noted in some of these
6 holes, also in these there were some perched water
7 tables but there is no hydrostatic water pressure
8 with depth.

9 In 1979 there were some slope
10 indicators installed at these locations and there
11 was another one installed at this location last
12 fall. These are instruments which make it possible
13 to measure ground movements with depth and I will
14 be talking about the measurements that have been
15 received from these instruments.

16 The other thing is that there is
17 quite a bit of water up in this bank over here.
18 There is water in this ditch over here, and some of
19 it infiltrates the existing grade and it exits as
20 surface seepage and causes some near surface movement
21 right up in this area here.

22 This is a brief summary diagram of
23 the types of movements that have been measured in the
24 Griffith slide area. This green line is for the
25 slope indicator along the existing track immediately
26 below the track grade, and it points out two things:
27 number one, the depth of movement is down to a level
28 of 40 feet, but the majority of movement is very
29 close to the surface, and that is also confirmed by
30

1 (Krahn)

2 what you see in the field and that the tree roots --
3 trees are uprooted and there is some shoving and
4 pushing very close to the surface.

5 Above the existing track there has
6 been only about one to two inches of movement over
7 a period of three years, and this is also further
8 evidence of this in that there has been some lifting
9 of the track required over the year, but it has
10 not been a problem.

11 Then, there has been limited
12 information obtained along the new grade suggesting
13 that there might be some movement, but we need some
14 more data and some more readings on that before
15 we can conclusively confirm that there is movement
16 there.

17 The new bank that will be constructed
18 over here will improve the stability of potential
19 sub-surfaces like this. Factor of safety is a measure
20 of the degree of stability. The higher the number the
21 more stable the slope, and if we take, for example,
22 a typical slip surface like this without this
23 embankment here we have a factor of safety of 1.17
24 and with it, 1.25. Another example of this blue
25 line here going from this point to this point, there
26 is also increase in stability. So that this
27 construction here will improve the stability. Those
28 numbers are not large increases, but for a very
29 slow movement such as three inches over a year or
30

1 (Krahn)

2 something like that, these numbers are adequate to
3 stablize that type of movement. There is, of course,
4 this sliding that goes on right on the surface and
5 that can be mitigated or halted by control of
6 surface drainage. The proposal to control the
7 surface drainage is briefly illustrated here.

8 There are two streams on the edge
9 of the Griffith slide coming into this area, and
10 these will be flumed across this area between the
11 two slides and then down to the flood plain.

12 I was talking about the seepage in
13 the banks up in the area. Horizontal drains will
14 be installed in there, and that water will be
15 directed into a drainage ditch. Also, this ditch
16 will be lined in order to prevent or decrease, rather,
17 the infiltration and then the near surface movement
18 and the active lobe.

(Krahn)

This will be taken over to a flume and also another stream in here and then flumed down and across the new line as well.

In our reports we have said at one time that this stream over here went on to the unnamed slide. In actual fact, it does not. It comes between the two and it was thought that this was infiltrating the unnamed slide but regardless of where it is this flume will control that infiltration.

Moving on to the unnamed slide, again geological studies by Thurber Consultants indicate that there is some landslide debris here and some glacier material here and that this is quite shallow. The best piece of evidence of the stability of this land slide is that this existing line has been operated here for a long, long time without any difficulty, indicating that things are stable.

There was a slope indicator installed in here last fall and there has been no indication of any movement and no measurement of movement so far. Also the new grade, there will be some fills and there will be some cuts throughout the unnamed slide area or the unnamed slide, but the mass balance in the unnamed will not change. This material will be moved around a little bit but material will not be added to it and material will not be taken away, and since it is

1 (Krahn)

2 stable and there will be very little change
3 here, the present stability will not be disturbed.

4 This one slide as well, I should
5 say, there is no well defined water table in this
6 region. There are some perched water tables
7 but no hydrostatic pressure with depth.

8 Moving to the wet area slide
9 between Surprise and Stoney Creeks, this slide
10 does not reach the existing line. Only the new
11 line crosses it. It comes up to it.

12 In this area the biggest problem
13 is the ground water. It is either at the surface
14 or very, very close to the surface. The materials
15 in here, however, are sand and gravel -- good
16 competent material. There is quite a bit of
17 seepage up in this area here, water in the ditch,
18 and that seepage is coming through here infiltrating
19 and arising here as springs.

20 There are at least four areas
21 where there are springs and these will be collected
22 with flumes and taken across the new grade and by
23 collecting the water, the general ground water
24 levels will decrease in this area, and this will
25 then be taken down to the flood plain.

26 One of these has already been
27 installed and it was installed last fall and has
28 been carrying substantial amount of water this
29 spring. For final design this one will be
30 upgraded to a slightly better standard but as it

Now the other thing that will be done in this area is to keep these two to one slopes stable. This ditch will be here to collect any surface run-off and it will be directed to the side. There will be some horizontal drains. That will be directed into ditches and then in through culverts and then down on to the flood plain. Also to lower the water table in this area, these

PM-B-4

1 (Krahn)
2 will be a french-type drain - gravel in here with
3 perforated pipe along the ditch, and this water
4 that is collected in those pipes will be taken
5 through the grade and across here at regular
6 intervals.

7 Just a general comment about
8 stability of cuts and fills: an extensive
9 computer analysis of stability was carried out
10 and this summarizes the results. Very briefly,
11 it shows that one and a half to one slopes
12 can be constructed up to a height of approximately
13 80 feet. If they are higher than that, they should
14 be flater than one and a half to one. The other
15 thing is that this graph shows that if we have
16 lower height slopes then we should be able to
17 construct them at a steeper angle. This is not
18 recommended because if they are any steeper than
19 one and a half to one slopes are prone to surface
20 sluffing during periods of heavy precipitation,
21 and other factors that control near surface
22 movement. So the steepest recommended slope
23 for the cuts and fills is one and a half to one
24 for heights up to 80 feet, and if they are higher,
25 then they are slightly flatter.
26

27 That is my brief summary of the
28 analyses and considerations that were undertaken
29 for the land slide areas.
30

1 (Buck)

2 MR. GEOFF BUCK, (Thurber Consultants):

3 Panel Members, Ladies and Gentlemen:

4 I am going to now describe briefly, I hope, the
5 hydrology and debris flow studies that were done
6 for the 10 major stream crossings for the proposed
7 grade in the Beaver Valley.

8 The setting is shown here -- it is
9 on the slope of the Selkirk Mountains that the
10 project is located and the peaks rise to 11,500 feet
11 such as Mount Shaunessey shown here, and the weather
12 comes in from the west so this site tends to be
13 in the rain shadow of those very high mountains,
14 but the catchment areas, of course, are up there.

15 The Beaver River Valley slopes
16 are intercepted at regular intervals by the
17 hanging valleys that I just described previously,
18 and the creeks have middle reaches containing
19 glacial till deposits, and these deep sided valleys
20 such as shown here at Surprise Creek, the stream
21 has incised up above and deposited the debris cone
22 in this area.

23 There are six such streams on this
24 route. They come from relatively small drainage
25 basins. There are two streams which are from
26 large drainage basins. This is Cupola Creek, and
27 there is also Mountain Creek, and they have the
28 hydraulic characteristics of rivers. There are
29 two streams intermediate between these extreme types
30

PM-B-6

1 (Buck)

2 and they are Alder and Stoney Creek.

3 So that is the stream setting.

4 The problem, of course, is to size a safe opening for
5 the stream crossings and taking into consideration
6 both the hydraulic capacity and the possibility
7 of debris flows. To set the scene just a bit
8 further, this is just giving you the precipitation
9 data that is available. It is excellent data
10 developed by the Parks in their avalanche control
11 work, and you can see here we have got a relatively
12 small portion of the total precipitation is in
13 rain and often the rain comes in the fall, in say
14 September, and, of course, very high precipitation
15 in the form of snow.

16 So going to the hydrology study
17 first, the larger streams, that is Mountain Creek
18 and Cupola Creek, there are many streams which
19 are gauged in the area which have comparable
20 sort of drainage areas, and so we can go to
21 stream-flow records and pick out the maximum
22 instantaneous run-off for those streams, and you
23 are getting values in the range of four to five
24 meters cubed per second per kilometer squared
25 of drainage area. So for those larger streams
26 we do have available data.

27 Now I would just note here,
28 interestingly enough, most of these large streams
29 the floods tend to be related to snow melt,
30 but this particular one happened in September,

1 (Buck)

2 so obviously you can have rain floods that are
3 the result of rain storms, and these are fairly large
4 streams, let us say in excess of a 100 kilometers
5 squared drainage area. When you get down to the
6 very small stream such as say Cedar Creek, which
7 has a drainage of 1.6 kilometers squared, well
8 it is the rainfall that governs and this data
9 really does not apply to such a small drainage
10 area.

11 So again just to illustrate that
12 information, we have good information for streams
13 that have drainage area in excess of 100 kilometers
14 squared. In this area, we have got values and
15 they come out at about maybe five or six meters
16 cubed per second per kilometer squared run-off,
17 but our problem then is what do we do for the
18 remaining eight of our ten streams which are in this
19 area here.

20 Well, without going through all
21 of the details, it was a question of considering
22 the slope of the basins, the size of the basins,
23 arriving at a coefficient run-off and considering
24 the concentration times to prepare an estimate
25 of stream run-off in the smaller basins. The
26 predictions were made on that basis using the
27 rational method of assessment and the values
28 fitted together rather well. In other words, the
29 historical data that was found for the large streams
30

1 (Buck)

2 when extrapolated down following fairly well
3 accepted mathematical relationships wound up
4 with stream values, design floods, which fitted
5 in well with what was arrived at by the rational
6 method. So we now have a design flow, and we can
7 size the openings, except for the fact that some
8 of these streams are susceptible to debris flow.

9 So first I should describe to you
10 what a debris flow is. A debris flow is a rapid
11 movement of a slurry of soil, rock and wood debris
12 mixed with water down a steep gradient. This is
13 a debris flow on the flanks of Mount McDonald within
14 the pass.

15 The debris flow events in the
16 area were mapped. This is the project area and
17 these numbers indicate where debris flows were found.
18 They were located first by an air photo interpretation
19 and then by helicopter reconnaissance to determine
20 the nature of the flows that happened in these
21 areas.

22 So just briefly to reiterate what
23 is required to cause a debris flow, you require a
24 steep channel, a steep gradient to the channel
25 banks that are providing debris such as these
26 as cut banks; the debris accumulates in the valley
27 here over the years and then some event will
28 happen -- it is usually an intense rain storm causing
29 maybe a slip of this bank; that breaks away, and
30 with its momentum carries on down the stream,

1 (Buck)

2 accumulating debris as it goes and this material
3 would then arrive and be deposited on the debris
4 cones that I mentioned previously. So an
5 affirmation of the volume of flows, and to a
6 lesser extent, the frequency of the flows. It is
7 estimated that at Stoney Creek the flows may have
8 a frequency of maybe once every ten years, whereas
9 Surprise Creek it may be once in 40 years.

10 So with these two pieces of
11 information, we can then go to applying this to
12 the design of the openings. I should mention
13 here that all of these streams are crossed by
14 existing bridges, and so you might ask: well,
15 why do the study? The fact is that several
16 of these bridges and existing lines are high-level
17 crossings where flood flow or debris flow has no
18 consequence. Where at the existing crossing,
19 they are low-level crossings. The low-level
20 crossings are controlled by the geometry of the
21 slope and the requirements of the railroad gradient.

22 To summarize then, going from
23 Cupola Creek and Mountain Creek, they are mountain
24 rivers where we have bridge spans and guide banks.
25 The piers set down against scour protection. We
26 have the intermediate streams like Alder Creek,
27 Stoney Creek. In the case of Stoney Creek the
28 bridge is well clear of the stream and there is
29 no concern about hydraulic capacity. In the
30 case of Cedar, Raspberry and Surprise Creeks

PM-B-10

1 (Buck)
2 these are debris flow prone streams and debris
3 resistant structures are proposed there, possibly
4 more from Mr. Fox on Cedar Creek. This is Surprise
5 Creek and this will be placed through a concrete
6 box culvert, which is debris flow resistant. Here
7 we have Stoney Creek, which, as I say, is going
8 to be crossed by a high structure, and finally
9 there is Connaught Creek, which is in a bed rock
10 canyon, and this rather beautiful scene shows the
11 stream. The crossing will be upstream of this
12 and well clear of the stream.

13 Thank you.

14 MR. JOHN FOX, (C.P. Rail):

15 Mr. Chairman, Members of the Panel.

16 My talk this afternoon is entitled "Design
17 Presentation". AS you must appreciate, it is
18 very difficult to summarize a project of this magnitude
19 and complexity in several hours, let alone 20 minutes,
20 particularly when you could understand that we have
21 taken roughly the past six months to design it.
22 However, I will attempt to highlight the 5th
23 Design we are presenting here and give the
24 pertinent details that influenced the final decisions.
25 Further site specific details have been and will
26 be discussed in the presentations by the hydrology,
27 geotechnical, visual impact and reclamation
28 specialists.
29

30

$$(Fox) =$$

The design of the Rogers Pass surface route was a sequential process using all available design techniques and mitigative measures to develop a realistic design that respects the integrity of the existing environment and the highest engineering practice. During the design process, C. P. Rail engineers worked in close collaboration with landscape architects and reclamation specialists on developing optimum environmental and engineering solutions.

Considerations were given to:

- 1) Maximum horizontal curvature of 6 degrees, Maximum grade of 1 per cent compensated for curvature;
- 2) Adequate clearance and bridge design at stream crossings which considered both river design discharges and debris torrents.
- 3) Slope stability, ground water control and soil preparation;
- 4) Design of cut and fill slopes and retaining structures;
- 5) Visual impact and overall terrain impact;
- 6) Completely balancing earth quantities within the park; existing steep slopes, landslide areas;
- 7) Ground water clearances and frost protection;
- 8) Coordination of activities

1 (Fox)

2 in the construction schedule, and

3 9) construction of a permanent
4 facility.

5 Primary consideration was given in
6 design to constructing the railway standards.
7 However, environmental considerations had the most
8 significant influence on the selection of the proposed
9 design and detailed route selection.

10 Despite the engineering constraints
11 to maintain structural and overall adequacy, the
12 alignment and design were modified to minimize
13 the visual impact. Environmental considerations
14 and impacts generally decided the proposed design and
15 location. Reclamation procedures, balanced earth
16 quantities and schedules to environmentally acceptable
17 standards were developed.

18 I would now like to present the
19 specific aspects of the surface route design.

20 Station 0+00 to Station 103+00:
21 I might say that these slides are the same as we
22 have around the room if anybody is interested
23 after, they can take a look at it. This section
24 of the line will be outside Glacier National Park.
25 From Station 0+00 to 70+00 the line will be on a
26 relatively flat terrain and will not be seen from
27 any of the key observation points. The alignment
28 was constrained by the requirement for adequate
29 clearance over Alder Creek.
30

(Fox)

1
2 From Station 70+00 to 103+00, the
3 Beaver River is on the west side of the valley
4 against the base of the slope. The existing
5 mainline has been built into the steep rock
6 terrain just above the river. The proposed
7 alignment had two alternatives:

8 1) Relocation of Beaver River
9 and placement of large fills in the existing channel,
10 or,

11 2) Relocation of existing mainline in
12 large rock cuts further into the slope to accommodate
13 the proposed alignment without encroachment into
14 the river.

15 It was decided that placement of
16 fills into the river would have a much greater
17 environmental impact than relocation of the existing
18 mainline further into the slope.- Large rock cuts
19 resulting from the relocation are very visible
20 from the two viewpoints on Heather Hill, but after
21 exhaustive study it was realized that there is
22 little that can reasonably be done to reduce the
23 visual impact at this point.

24 Station 103 to 141:

25 In this section, the proposed
26 alignment runs along the base of the mountain slope
27 and then along the margin of the Mountain Creek
28 fan.

29 The alignment has been designed
30 on fills utilizing material available from the

1 (Fox)

2 relocation at station 70 to 100. This reduces
3 the number of visible cuts resulting in a relatively
4 small visual and terrain impact, even though this
5 area is highly visible from the Heather Hill
6 viewpoint.

7 The alignment was constrained by the
8 requirement for adequate clearance and orientation of
9 the crossing at Mountain Creek.

10 Station 141 to 176:

11 In this section, the design was
12 restricted by: keeping the line as far from Mountain
13 Creek campground as possible between station 163 and
14 176, minimizing the size of fills in the gully
15 between station 163 and 176. The alignment through
16 the Mountain Creek Terrace was considered
17 acceptable because there already is an existing
18 scar and the granular materials have been reclaimed
19 successfully in the trials conducted in 1982 on
20 existing cuts. Top dressing this material as
21 presently proposed will further enhance the reclamation
22 of the new grade cuts. The alignment also permits
23 the construction of a noise berm to preserve the Park
24 experience for campers as well as preventing vehicle
25 access to the track. Upslope retaining walls will
26 be built near station 176 to minimize the extent of the
27 cuts.

28 Station 176 to 200 - this is the
29 Griffith Slide area:
30

1
2 (Fox)

3 The proposed line crosses a moderately
4 steep sideslope with relatively shallow soil cover.
5 The alignment was maintained in shallow cuts
6 as dictated by the terrain. Any relocation upslope
7 or downslope would result in either large cuts
8 or large fills which are both unnecessary and
9 undesirable.

10 Station 200 to 250, and this is
11 also the Griffith and unnamed slides:

12 The engineering constraints of
13 crossing the slide areas necessitated making use
14 of fills and minimizing cuts wherever possible.
15 Large fills were, therefore, designed on the
16 Griffith and unnamed slides which maintained and
17 improved the stability of these ancient landslides.
18 The large gully between the two slides is abrupt and
19 had to be crossed with large fills. Any attempt
20 to avoid fills across the gully resulted in
21 undesirable cuts through both of the slides.
22 However, this section is less visible than most
23 and the large fills were considered visually and
24 environmentally acceptable.

25 Station 250 to 263:

26 Between the unnamed slide and Cedar
27 Creek, the slopes are quite steep and bedrock is close
28 to the surface. The design calls for relatively
29 small cuts in rock since the steep slopes would
30 result in large fills and the loss of considerable

(Fox):

vegetation. The design was severely constrained by the Cedar Creek crossing. Cedar Creek occurs on the crest of a very high and steeply sloping debris cone. Given the geometric constraints, the alignment would have to be relocated a distance of 100 feet away from the mountain side for more than 500 feet on either side of the creek to provide adequate clearance for a crossing on top of the debris cone. This would result in loss of a considerable amount of vegetation with proportionally large terrain impact. As a result, the design was carried through the debris cone with the planned creek diversion to the west. Due to adverse environmental impact on beaver, and when I say beaver that is not the Bēaver River -- those are the little beggars that come in and make a nuisance of themselves, an alternative proposal was presented for training the creek in its present location. Both proposals are shown on the wall panels, and I am not recommending the east channel alignment with the creek channeled in its present location. That is going to be dam costly and that is what we are going to do to save three beavers.

Station 263 to 294 (Raspberry Creek)

Between Cedar Creek and Raspberry Creek, the slopes are steep and bedrock is close to the surface. The major design constraint along this section was the provision of adequate clearance at Raspberry Creek. The design calls for cuts in

1 (Fox)

2 rock since large fills on steep slopes would
3 result in loss of considerable vegetation. Most
4 of this section was not very visible and the
5 design concentrated on minimizing the terrain
6 impact. Fill sections were required on the
7 approach to Raspberry Creek to provide the required
8 clearance at the stream crossing. Downslope retaining
9 walls were not feasible due to the attendant stability
10 and construction problems encountered with large
11 downslope retaining walls in steep terrain.
12 Retaining walls are also not necessary since the
13 fills are not visible from observation points.

14 Station 294 to 332 (Surprise Creek):

15 Between Raspberry Creek and
16 Surprise Creek, the valley slopes are very steep with
17 bedrock close to the surface. The design was
18 constrained by the requirement for adequate clearance
19 at Surprise Creek will minimizing fill sections on
20 either side of the creek. A siding will extend
21 from Station 317 to Station 412 a short distance
22 east of Stoney Creek. The design minimized the impact
23 by designing cuts in rock with retaining walls, although
24 the additional subgrade width for the siding dictated
25 fairly large rock cuts. Although the design
26 attempted to keep the large fills to an absolute
27 minimum to prevent loss of large amounts of vegetation,
28 the very steep terrain and occasional gullies made
29 it impossible to avoid all fills as the cuts on
30

1 (Fox)

2 alternative alignments became prohibitively large.
3 Construction of downslope retaining walls was
4 evaluated but found to be unfeasible due to the
5 very steep terrain. However, the extent of the
6 cuts will be limited by the design cuts in rock
7 with upslope retaining walls. Downslope retaining
8 walls are again not necessary since the fills will
9 not be visible from observation points.

10 Station 332 to 384 (Wet Slide area):

11 The valley slope between Surprise Creek
12 and the wet slide area is very steep, irregular and
13 dissected by numerous gullies and snowslide paths
14 giving the slopes a corrugated appearance. It was
15 found to be impossible to design the alignment totally
16 in cuts or fills due to the depth of the gullies.
17 A balanced cut and fill design was adopted.
18 This results in alternating large cut and large
19 fill sections with the additional subgrade width
20 for the siding. Retaining walls could not be
21 successfully employed due to their required size
22 and the extremely high loads they would have to
23 carry. There was little that could reasonably
24 be done to minimize the terrain impact in this
25 location.

26 Station 384 to 426 (Stoney Creek):

27 The alignment crosses shallow slopes
28 of low relief on the wet slide from Station 387 to
29 Station 400. A grade line has been set for a
30

(Fox)

1 low fill which, together with extensive drainage of
2 the upper slope and subgrade foundations, give an
3 optimum design for this location. The ancient slide
4 area from station 400 to station 407+00 has been
5 gullied and a balanced cut and fill design has
6 been set.

7 To reduce the size of cuts and
8 fills beyond the wet slide area, downslope and upslope
9 retaining walls will be constructed between station
10 408 and 413. Seven hundred feet of bridge
11 structure will be built to replace the east approach
12 fill to Stoney Creek. This costly bridge alternative
13 vastly improves the visual impact and was implemented
14 since this is one of the most visible sections
15 of the proposed alignment.

Station 426 to 497, the east portal of the short tunnel. At Stoney Creek, the alignment is set to minimize the size of the large cut at Station 429. The terrain between Stoney Creek and the short tunnel is very steep and irregular. A variety of alternatives were considered in this section such as cuts and fills, upslope and downslope retaining structures and an elevated deck structure.

Since the valley slopes are as steep as 1.2 to 1, construction of cuts and fills to slopes of 1.5 to 1 were impossible since fills would extend down to the Trans Canada Highway and the cuts would extend a great distance up the mountain.

An analysis of various types of retaining walls indicated that it was impractical to construct any walls in excess of 30 feet in height, due to the large loads they would have to carry. As well, the existing slopes are stable but have a factor of safety of near unity. Construction of retaining walls along this section would be very difficult due to the limited access. Construction of a 6,000 foot elevated trestle with retaining walls located near Stoney Creek and in the east portal of the short tunnel is considered to be the most suitable design for this area.

Now, having said that, we are still

(Fox)

looking at that design. That is a mammoth structure to put in place. Whether it be concrete or steel has not been decided yet, but in any event, it might be that a little bit near Stoney Creek may be cut and fill with retaining walls, but certainly something of the order of 4,000 feet plus will be a structure.

Station 556 to 602, and this is the east portal of Rogers Pass main tunnel. The alignment exits the short tunnel at Station 556 and immediately crosses over Connaught Creek. The line from the creek to the portal of the Rogers Pass tunnel will be constructed entirely in fill taken from the tunnelling operations. The majority of the fill will be placed in the existing abandoned gravel pit.

The bridge, if anybody is worrying, is well above those Bear Falls, I believe they are called, and you will not even see the bridge when you are looking at the water dumping over the rocks there.

The earth quantities were calculated by computer and checked manually for verification. The stripping and waste material will be used for top dressing to facilitate reclamation. Contract specifications will specify that the material will be compacted to 95 percent proctor density.

Provisions in the contract will

(Fox)

require the contractor to handle material in a manner that prevents it from becoming wet. Similarly, construction in unsuitable weather will not be permitted. If material becomes too wet to place due to the contractor's mishandling, provisions will be made in the contract for the contractor to dry it. That ought to stop him.

In the event that wet material cannot be dried on the grade and it is too wet or otherwise unsuitable, it will be wasted. A suitable waste area exists on the upslope slide of the large fill between Stations 224 and 229.

A stockpiling area is proposed in the disturbed portion of the Mountain Creek gravel pit.

Bridge footings and culverts will be constructed during the late summer and early fall after the spring runoff peak and before winter freezeup. Because fish probably spawn in some of the streams in the Beaver Valley during this time period, measures will be employed to minimize the amount of sediment entering water courses during construction.

Cofferdams will be placed around bridge footing construction sites to prevent flooding if needed. Water removed from the excavations will be discharged into Mountain, Stoney or Connaught Creeks after being treated in settling ponds or

C-5

1 (Fox)

2 with hay bale filters, if necessary.

3 Smaller creeks will be diverted by
4 sandbag cofferdams well above culvert construction
5 sites so as to keep the sites as dry as possible.
6 Water will be returned to the stream below the
7 construction site. Hay bales will be placed across
8 the stream below the construction site but above the
9 entry point of diverted water to filter sediment
10 out of any water seeping into and through the
11 construction site. Hay bales and accumulated sediment
12 will be removed from the stream bed after culverts
13 and stream training works have been completed.
14 The cofferdams will then be removed from the streams.
15 Hay bales will be used to prevent sediment from
16 entering streams during backfilling operations.
17 Specialized reclamation measures to be used around
18 bridge footings and retaining walls will be discussed
19 in the reclamation presentation.

20 In summary, then, the alignment
21 that we present to you is the most refined of all
22 the designs and it is our best possible effort to
23 protect the visual integrity of Glacier National Park,
24 while meeting the engineering requirements of a high
25 capacity rail line.

26 Thank you.

27 THE CHAIRMAN: I would now like
28 to invite our technical experts to come up, Mr.
29 Hurwitz, I believe, you are probably going to be
30

C-6

1 (Adam)

2 the first one, and Mr. Adam, up here on the right,
3 please, to make your presentation.

4 MR. LARRY E. HURWITZ (I.D. Systems Ltd.): Mr. Chairman
5 Dr. Adam will read most of it and I will intercede a
6 little later on.

7 DR. KENNETH M. ADAM (I.D. Systems
8 Ltd.): Panel member, C.P. consultants, and ladies
9 and gentlemen, before I start I would just like to
10 say that I guess that we get paid for being critical
11 and I think our general impression on this project
12 at this stage is that there has been a lot of
13 excellent work done by a lot of consultants and
14 C.P. When we do come to the points of criticism,
15 they should be taken in that context, that there is
16 a lot of good work has gone on.

17 We are of the opinion that the
18 environmental process to date has progressed
19 satisfactorily. The Rogers Pass Environmental Hearings
20 in the spring of 1982 raised some valid concerns,
21 and C.P. Rail and its consultants have produced
22 some excellent work in response to those concerns
23 in the ensuing months. However, it is evident that
24 Parks Canada and others still have concerns about
25 effectiveness of some of the proposed environmental
26 measures and the ultimate effects of the project on
27 Glacier National Park.

28 We believe and sense from others,
29 the concern stems mainly from the lack of specificity
30

C-7

1 (Adam)

2 of environmental controls and commitment. This is
3 no condemnation of C.P. Rail. In fact, production of
4 the red book entitled "Rogers Pass Project:
5 Submittal to Federal Environmental Assessment Review
6 Officer, June, 1983" goes a long way towards
7 fulfilling commitments and detailing environmental
8 measures and controls. Most importantly, it
9 demonstrates C.P. Rail's willingness to make such
10 commitments and in itself is testimony to C.P.'s
11 recognition that such a document was needed.

12 One area of some concern to us
13 is the relative impression of the effectiveness of
14 restoration techniques of major terrain disturbances.
15 For example, C.P. Rail on the one hand cites
16 restoration at the Big Cut at Lake Louise as an
17 example of what can be done, while others cite it
18 as an example of unsuccessful restoration. Again,
19 what is missing is an agreed or specific definition
20 of what constitutes success or failure. A
21 specification such as "restoration shall be deemed
22 successful once 75 percent ground cover is established
23 over 90 percent of the area that can reasonably be
24 expected to be revegetated", would at least bring the
25 problem into qualitative rather quantitative terms.

26 Another area of concern to us is
27 that either C.P. paints too rosy a picture of the
28 aesthetic qualities of post-construction right-of-
29 way conditions or Park Canada's expectations are
30

C-8

1 (Adam)

2 too high. Probably the true picture is somewhere
3 in between. However, we believe some problems are
4 created by overly optimistic presentations that
5 raise expectations.

6 As an example, the Visual Impact
7 Assessment Report using the computer graphic
8 photomontage simulation technique is a genuine
9 attempt to aid Parks Canada and others to
10 visualize the terrain impacts and their effects on
11 aesthetics. However, the use of black ink and
12 dark color shades for overlay unintentionally
13 obscures the picture. In summer and for sure in
14 winter with snowcover, denuded cuts and fills will
15 appear in much lighter colours than the surroundings.
16 We have prepared an overlay that accentuates that
17 problem, and you are free to look at that later, if
18 you so desire.

19 Unless Parks Canada realizes at this
20 time the vividness of the colour contrasts caused by
21 exposed terrain impacts as will be seen from the
22 Trans Canada Highway, they are bound to be disappointed
23 with the end product regardless of C.P. Rail's good
24 efforts to mitigate it.

25 Other visual realities pertain to
26 car passengers farthest from the new grade, that is,
27 the driver's side in westbound vehicles, and the
28 passenger side on eastbound vehicles. They will
29 focus directly on the new disturbance in many
30 locations.

C-9

1 (Adam)

2 This is a result of mountain tops being blocked
3 by the interior roof lines, valley bottoms being
4 blocked by the interior door lines, and the cross-
5 valley view of the Trans Canada Highway being the
6 only side view available.

7 Environmental inspection is also
8 a concern to us. It is not reasonable to expect
9 an Environmental Coordinator can inspect all
10 construction activities. Crisis type problems alone
11 will occupy the Environmental Coordinator almost
12 full time. Should construction involve two and
13 possibly even three work shifts, one environmental
14 inspector would be run off his feet. Our experience
15 with environmental inspection is that an independent
16 environmental inspector should be available for each
17 concentrated work front, that is, bridge construction,
18 cut and fill, tunnels, et cetera. The Environmental
19 Coordinator should oversee the environmental
20 inspectors and be available for crisis situations.

21 The right of job shut-down must be
22 available to the Environmental Coordinator if the
23 environmental inspectors are to play a significant
24 role in project control. We do not think C.P. Rail
25 should necessarily be burdened with the cost of such
26 inspection, but that Parks Canada has responsibility
27 to project the Park.

28 Training of contractors and their
29 workers about environmental matters and continual
30

C-10

1 (Adam)

2 reminders of the need for environment protection will
3 be required if C.P. Rail commitments to environment
4 protection are to be realized. The soft-sell
5 approach to workers seems to be most effective in
6 our experience, because otherwise workers tend to try
7 to beat the system or to pull one over on inspectors.
8 A sense of team effort to protect the environment
9 where workers control themselves is the preferred
10 method.

11 Irrespective of environmental
12 inspection and engineering and/or environmental
13 specifications, Murphy's Law will apply. If
14 something can go wrong, it will go wrong. Slides
15 during construction or the need to waste wet materials
16 will almost surely arise. Just as at Lake Louise,
17 unforeseen problems will necessitate requests for
18 deviations from plans and such requests should be
19 anticipated by Parks Canada.

20 A mechanism to deal with such
21 problems should be left in place by the Panel. We
22 also envision the need for an annual independent
23 inspection of the project. These two needs could
24 be filled by the existing Panel, but we understood
25 FEARO Panels disband after submitting their final
26 report. Therefore, we recommend that the
27 Environmental Committee continue until three years
28 after completion of the project to fulfill a
29 continuing and post construction inspection review.

(Adam)

Now turning to hydrology. Work on hydrology has progressed significantly in the past year. Design criteria have been established and and site specific recommendations have been made for major creeks to be crossed. Designs have been influenced by both hydraulic and debris flow estimates. In general, flow estimates were found to be conservative for design purposes. Over-design is justified in the terrain encountered, particularly since flow runoff records do not exist for the streams to be crossed. Where records of streamflow do exist for rivers or streams in the region they are either of short duration or for much larger drainage areas. Therefore, we agree with the conversative approach taken. However, on the other hand, over-design will result in extra training works and guide banks that will add to aesthetic costs. There is still a need for further details related to training works and guide banks including aesthetic assessment.

At least two potential problems remain and another problem already exists. They are capacity of temporary bridges; what to do with Cedar Creek; and siltation downstream of existing and future terrain disturbances. The capacity of temporary bridges has been a concern, however, all are now in place, although the one over Mountain Creek was threatened this spring. Because they are

C-12

1 (Adam)

2 already in place, there is no reason to replace any
3 that may be under capacity until necessitated by
4 washout if that should occur. To upgrade at this
5 would probably cause as much environmental damage
6 as washout and replacement. Therefore, we recommend
7 no action be taken on temporary bridges except
8 maintenance.

9 Now, with respect to Cedar Creek,
10 I will probably deviate from my notes and just leave
11 it at this time. I have for the first time seen the
12 proposal at Cedar Creek and I am in general agreement
13 with the recommendation that Mr. Fox made at
14 this time, without having gone into it in detail.
15 I think it is probably the best attempt that could
16 be made at keeping it within or close to its normal
17 channel, and in that respect, I like it much better
18 than the west alternative.

19 The existing problem that I
20 referred to earlier relates to siltation of streams,
21 stemming largely from the fill material of the
22 temporary access road, and in future from the new
23 railway grade, washing directly into streams. Other
24 such projects such as pipelines and mine development,
25 often just on Crown land, are required to meet
26 certain standards through the use of sediment traps
27 or other means.

28 Visual monitoring has been proposed
29 by C.P. Rail. However, a more specific standard is
30

C-13

1 (Adam)

2 needed and we suggest the mining standard should
3 apply, that the total suspended solids should be
4 limited to 50 milligrams per litre maximum absolute
5 or ten milligrams per litres above the natural
6 background concentration, whichever is greater.

7 Natural background concentration
8 should be measured immediately upstream of terrain
9 disturbances for comparison to concentrations within
10 100 metres downstream of the disturbance.

11 C.P. Rail is committed to limiting
12 tunnel effluent to 60 parts per million or 10
13 parts per million above receiving body concentration,
14 whichever is greater. Such effluent flows are
15 normally diluted by stream flows. Therefore,
16 limiting streamflow suspended solids concentrations
17 to 50 milligrams per litre or 10 milligrams per litre
18 above natural background concentration is not
19 unreasonable. This stipulation will require
20 periodic, minimum twice weekly, monitoring, both
21 upstream and downstream and may result in the need
22 for sediment traps, revegetation of temporary fills
23 and the use of natural forest cover for filtering
24 sediment out of drainage flows.

25 Another concern relates to C.P.
26 Rail's commitment towards slope stabilization,
27 temporary bridge removal and reclamation in the event
28 the Crow Rate controversy delays or suspends present
29 construction plans. We believe this possibility must
30

C-14

1 (Adam)

2 be addressed by both C.P. Rail and the Panel.

3 Finally, our last general concern
4 relates to spending dollars committed to environmental
5 enhancement or protection in an efficient manner.
6 As an example, we do not in general find rock cuts
7 offensive and view attempts at their reclamation as
8 inefficient and unnecessary. Therefore, we would
9 eliminate hydroseeding rock cuts as well as the
10 proposed use of dark asphalt tackifier.

11 MR. HURWITZ: I will continue,
12 Mr. Chairman, with the terrain aspects, and I really
13 have set this up simply to clear up some of the
14 outstanding items related to the 27th of April
15 submission to the Panel after reading the documentation
16 of C.P.'s.

17 The first item is on the right-of-
18 way. I had requested the area of the right-of-way
19 which would be required and its relationship to the
20 60 metres or 200 foot width that was approved by
21 the CTC. Now, in the red book, C.P. Rail has
22 indicated a variable width of right-of-way, which
23 is obvious when you look at the plans, which will
24 occupy about 371 acres of park lands, although
25 that total amount will not be cleared.

26 In trying to put the number in
27 perspective, we have calculated or tried to rationalize
28 the number and have calculated an average width
29 of right-of-way to be 323 feet with about 156 feet
30

C-15

1 (Hurwitz)

2 cleared. This is a number, for the benefit of
3 the Panel and for the benefit of Parks Canada, just
4 to know what they are dealing with. I have had
5 to make certain assumptions to come up with it, and
6 perhaps it seemed the fact the right-of-way was
7 double the cleared width seemed a little difficult
8 to explain, and perhaps C.P. Rail could comment.

9 We would also ask what alternatives
10 have been considered in location of major cuts and
11 fills which might reduce right-of-way width
12 requirements. C.P. Rail has described the design
13 considerations, which Mr. Fox just went through in
14 considerable detail. Retaining structures were
15 considered in many instances to reduce fill
16 requirements that were deemed unfeasible due to
17 stability and construction problems in the
18 steep terrain, and the high loads for which they
19 would have to be designed.

20 Now, while these are reasonable
21 statements, it still appeared that certain fills
22 in the section particularly between Station 294 and
23 284 might be reduced with the use of walls no higher
24 than those that have presently been placed at the
25 east portal of the main tunnel. I acknowledge that
26 there would likely be a cost premium, that it might
27 be possible to save something like 100 feet or more
28 of clearing in certain locations, and possibly C.P.
29 could elaborate somewhat on that.
30

C-16

1 (Hurwitz)

2 The borrow materials item, I noted
3 up here, something I had not seen before was a
4 materials handling charge. Certainly I have a
5 concern about the wasting of wet materials, as I am
6 sure Parks Canada has from the previous experience,
7 and I think C.P. is readily aware of the problem.
8 I would, however, recommend to the Panel that some
9 mechanism which would ensure that Parks Canada have
10 input and/or review of contract documents prior to
11 tender. The grade construction operation must be
12 spelled out carefully and completely in the contract
13 documents so that contractors will know where
14 materials can be disposed of.

15 In other words, what we are trying
16 to achieve is ask C.P. to spell out where the waste
17 areas will be and no others will be allowed, so
18 that in the heat of the construction program, after
19 it has been raining, the contractor will not want
20 to start taking ad hoc measures to waste the material.

21 In drainage, again I saw today for
22 the first time plans and so on of the drainage flumes,
23 plus Dr. Krahn's description of the drainage across
24 the Griffith, unnamed and wet landslide areas. I
25 feel I have that well under control. The measures
26 seem very sensible, very satisfactory. Again, it is
27 a disturbance that will occur off right-of-way, and
28 the question I had posed in here is minor but simply
29 to make Parks Canada aware of the situation, as to
30

C-17

1 (Hurwitz)

2 what additional area might be required in terms of
3 the disturbance if it is not already included in
4 the right-of-way figures on page 49.

5 The hydrology Ken has covered fairly
6 completely. In some of the guide bank requirements
7 for some of the streams, again, it is an off right-of-
8 way disturbance presumably and will require some
9 additional clearing, and could some indication be
10 given of how much that is.

11 The final concern with the previous
12 letter was the tunnel wastewater treatment. The
13 red book has handled that completely, as far as
14 I am concerned, and we have no further concerns about
15 that.

16 I would like to reiterate what Ken
17 has said, that things have gone a long, long way from
18 last year and the work has been done in an excellent
19 fashion. Thank you.

20 THE CHAIRMAN: Thank you very much
21 for the presentation.

22 Before we stop for coffee break,
23 I will ask our last technical expert, Mr. MacDonald
24 to come up and make his presentation and then maybe
25 we will get you all back up after coffee break.
26 I believe after coffee break also we will be
27 starting with a very short presentation by Parks
28 Canada.
29

30

C-18

1 (MacDonald)

2 MR. C.R. MacDONALD (National
3 Capital Commission): Members of the
4 Panel, C.P. Rail, ladies and gentlemen, last fall
5 I was asked by the Panel to take a look at the
6 proposed route for this project, particularly the
7 service route and I made the inspection at that
8 time and my instructions to the Panel at that time
9 was that there was no problem constructing a rail
10 along this terrain from the point of view of
11 engineering.

12 As a result, I will not go into
13 a lot of technical details because based on my
14 previous experience, the soil was exposed at the
15 time the access road was available to drive over,
16 and it was obvious the material from the slopes
17 from an engineering point of view would allow a
18 railway to be built. So I make this statement here
19 because my notes were thrown together over the last
20 few nights, the last ones about two o'clock this
21 morning, and possibly further on it may be
22 misconstrued, my reference to two to one slopes.

23 So I will go on from there to say
24 that after the trip last year I said the route was
25 feasible. There were a few slides areas that would
26 require special attention that some of the experts
27 have addressed today, but even at that time there
28 was nothing to alarm me that good engineering technique
29 could not handle.

30 My biggest concern and the one I

C-19

1 (MacDonald)

2 expressed to the Panel, particularly the Chairman,
3 was that environmental reclamation was going to be
4 very difficult in that terrain, and that was my
5 biggest concern and most of my remarks were aimed
6 at that particular point.

7 Our experience over the years is
8 that any slope under two to one, you have very little
9 success with revegetation. I make that statement
10 very categorically.

11 For this reason, I suggested that
12 the Panel ask for a visual impact area concentration
13 with the view that none of us want to see money spent
14 in vain, either by C.P. Rail or anyone else if the
15 results are still going to leave you a scar. If that
16 is the possibility, then let us live with the scar
17 the same way as you live with the avalanche scars
18 that nature makes.

19 So it was for that reason I asked
20 that, okay, if you can concentrate on the areas that
21 are highly visible, let us put our money there if we
22 can. That was the intent. I also commented at the
23 time, as I recall there was concern about the
24 15 metre limit for an access road and there was no
25 question that that had to be acceded to in that
26 terrain.

27 I also said that site cross-sections
28 were really required for me to make any comment on
29 whether or not workable slopes could be achieved with
30

C-20

1 (MacDonald)

2 or without retaining walls, and retaining walls
3 are expensive, there is no question about that.

4 With this background in mind, there
5 has been a lot of studies, as Mr. Adam pointed out,
6 and the problems have certainly been addressed and
7 over the last five days I have crammed the various
8 reports as much as possible into my head, and the
9 Panel's experts comments, and my concerns are
10 as follows. I do not feel I can separate terrain
11 impact, hydrology, erosion control and visual impact
12 assessment separately. They are inter-related and
13 I will proceed on that basis.

14 It is important to emphasize that
15 with my past experience I look at the total project
16 which I was just saying, so if I make comments in
17 certain areas where you have other advisors, no
18 offence intended. If we are all in the right ball-
19 park, we will probably agree anyway.

20 In the case of slope stabilization
21 and erosion control, drainage, revegetation, they are
22 all interdependent, the Visual Impacts Assessment
23 Study was very thorough, but I must admit I was very
24 surprized at the number of impact areas, that is
25 visual impact areas, and the fact that the design,
26 despite retaining walls, was mostly one and a half
27 to one.

28 In regard to revegetation, I am sorry,
29 but notwithstanding consultants' reports and studies
30

C-21

1 (MacDonald)

2 and assurances and theory, human beings
3 construction practice, as Ken pointed out and Larry,
4 problems that develop in construction, the reality
5 is that if you do not have a slope of two to one
6 or better, your chance of reclamation is very low,
7 very low and you then turn around and say if you
8 cannot do it, then do not waste money trying to.
9 Live with the rock face; live with the fact that
10 you are going to have a certain amount of scars.
11 That is the price you have to pay.

12 The increased slopes greatly increase
13 the erosion factor, so your mulch and seeding and
14 all your experts in reclamation, they do not even
15 get to bat, because the material ends up down in
16 the flood room.

17 I would suggest to the Panel, and
18 I think I already have, that if you look closely
19 at any of the steep slopes along your travels from
20 Revelstoke, you do not see a very high percentage of
21 revegetation on any of the slopes. They are very
22 scruffy and they look scruffy and that is the
23 situation.

24 So what we are dealing with is do
25 we ask that going through Glacier Park, you have taken
26 down all those trees, you have got to replace them.
27 In this day and age, I suppose one could say yes,
28 we should. You know, we are not 20 years ago; we
29 are not 50 years ago, but just the same my comments

(MacDonald)

here are directed at the fact that you need
everything going for you.

PM-D-1

(MacDonald)

1 If you start with one and a half to one slope,
2 I am sorry, and Mr. Walker is going to address
3 this tomorrow, you are starting with your hands
4 tied behind your back. I cannot even guarantee
5 with the slow growth season you have in Glacier
6 Park, and with some of the suggestions I will
7 make here that you will be successful. What I am
8 saying is you should try to.

9
10 So I suggest that you take another
11 look at trying to improving the slopes with
12 retaining walls.

13 The other aspect is even on the
14 one and a half to one, you will have to use some
15 kind of mechanical assistance to your revegetation,
16 whether that is chicken wire scathing fabrics,
17 you know, you name it. These are all expensive
18 also.

19 In its brief C. P. made reference to
20 a six-month construction season. Well, I do not
21 want to get into an argument on that but it is
22 fine for tunnel construction, bridge construction,
23 but I question whether you are going to have
24 six months working on the surface route. Construction
25 on side hill mountain terrain requires well
26 organized, well timed and site specific operations.
27 They also guarantee no slope area will be exposed
28 to the elements more than six months. If I am
29 not mistaken, that is in one of the articles.
30 I consider six months of bare slope too long. I

(MacDonald)

1 I realize some of the consultants have referred to the
2 fact that there was not too much erosion in some
3 of the soil. You are forgetting that these
4 embankments have to have some form of top dressing.

5 The success of the overall project is
6 also very highly climate related as a result of
7 snow, rain and a short and slow growing season.
8 I recommend that a construction schedule be
9 set up site specific for each problem area, taking
10 into account the best weather information and
11 I realize that is difficult in Glacier National
12 Park when setting the timing for each one.

13 Revegetation, the reclamation
14 should take place immediately upon completion
15 of the slope grading. This is equally important for
16 erosion control as it is for slope stabilization.
17 I do not agree that you have time for two planting
18 seasons. By this I am referring to fall. The
19 slow growth and the weather just does not allow
20 it. I would say you should plant on one, and by
21 that I do not mean that you cannot plant in June,
22 and you cannot plant in July, but there is a latest
23 date on which you should plant which, and I might
24 add at this point I had a few minutes with Mr.
25 Walker and he agrees that probably August 1st
26 would be the cut-off date.

27 In this respect possibly the
28 answer would be that you would have to have more
29 landscape crews to get the most done at the best
30

1 (MacDonald)

2 weather time with the obvious best results. This
3 is an opportunity for C. P. to get away from
4 the normal sequency of construction and develop
5 a different one more in keeping with climatic,
6 terrain and environmental requirements. This
7 system would of necessity be spelled out in the
8 contract documents.

9 In regard to bridges and the cuts
10 and fills and the waste material, the bridge
11 designs are certainly not showing much in the way
12 of imagination. However, I suppose their visual
13 impact in most cases is not all that significant.
14 However, I suggest a look at Stoney Creek and
15 esthetically there is certainly some room for
16 improvement, although yesterday Mr. McKnight
17 informed me that it is doubtful whether the long
18 viaduct will be that visual. If it is not, well
19 that is another aspect. If it is, then certainly
20 I would like to see a little more originality and
21 a little more input into the study to the design
22 of the long viaduct.

23 I am surprised at the amount of
24 stream training. However, I have reviewed most
25 of the bridge sites again and without grade
26 and alignment changes there is very little that
27 can be done. There may be enough play and I
28 would ask C. P. in this case to have a look at
29 it, to reduce the skew at mountain creek. The
30 only way you can do this, of course, is a bit of

(MacDonald)

1 an alignment change and with the restriction of
2 six per cent curve and one per cent grade, there
3 is not much, as I just mentioned, room to do so.

4 I reviewed the cuts and fills
5 from the Park boundary to the tunnel specifically,
6 and Mr. Hurwitz is quite sure and quite right
7 concerning the right-of-way. It not only exceed
8 200 feet but it exceeds 300 in numerous places.

9 I was pleased at the number of
10 times, surprisingly, that I found 1.75 to one
11 slope in use, because going to two to one will
12 not be all that difficult in those areas
13 particularly. At the same time that the adjustment
14 is made to two to one, the possibility of additional
15 retaining walls to reduce the right-of-way could
16 be looked at, although I did look at some of the
17 cross-sections myself and there, you know, there
18 are some that you cannot touch. The retaining
19 walls would be so high to try to achieve any
20 satisfactory result that it would be exorbitant
21 construction-wise and cost-wise.

22 Another concern I would have and that
23 has already been addressed is the waste material
24 referred to in one of the reports. There are
25 two types: the material contaminated with
26 clearing and grubbing operations and forming part
27 of the embankment of the access road, and the silty
28 excavation which is located in -- well, actually
29 a couple of specific areas, and as Larry just
30

1 dealt with, if it becomes oversaturated it becomes
2 unacceptable. The consultant recommends its
3 use, if I recall, as berms or top dressing, but
4 there were certain sections in the plan that I
5 saw the word waste used right in the fill, which
6 I consider a questionable procedure from the
7 slope's ability point of view. It is also not
8 clear who decides, and Mr. Fox just dealt with that
9 a few minutes ago, when material has had too much
10 moisture. Since this is highly climatic sensitive,
11 it is another argument for my site specific
12 construction program.

13
14 Dry weather operation in these
15 areas and you have less waste material. The
16 design philosophy for the Griffith Slide is the
17 same one I have used often for Ieda clay along
18 the Rockcliffe Banks home -- mass or weight at
19 the end of the slippage plain. As you know there
20 is a 1.75 to one. Well, of course, two to one
21 gives you additional mass. So obviously that
22 has an engineering advantage besides a revegetation
23 advantage.

24 In summary, my recommendations
25 are: 1) Site specific construction
26 scheduling clearing spelled out in the contract
27 documents. I consider construction control, and
28 it is very difficult, and with all the effort,
29 you know, you are still going to have slippage.
30 It is very important though in this terrain.

(MacDonald)

1
2 2) Vegetation of slopes to take
3 place as soon as grading is completed. No
4 excavation of embankment to be exposed any longer
5 than necessary but three months maximum and not
6 six.

7 3) Slopes to be two to one to
8 increase slope stability. Safety factor to reduce
9 sheet erosion and give reclamation methods
10 a fighting chance to succeed.

11 4) Scheduling of revegetation to
12 be aimed at giving the maximum time possible
13 for germination and rooting with a cut-off date
14 to be set by Mr. Walker -- I just discussed it
15 with him and it is suggested as August 1st.

16 5) Drainage control, of course,
17 is imperative not only in the slide areas but in all
18 side hill terrain. The designs, of course, to
19 be approved by Parks Canada. I am curious and I
20 might ask this just from an engineering point of
21 view, why no benching is used in some of the
22 larger fills.

23 6) Another look at reducing the
24 right-of-way by use of retaining walls. I do not
25 hold the most maximum of hope in this area, but
26 at least I think it should be looked at.

27 7) Alignment adjustment to
28 reduce skew at Mountain Creek, again, if at
29 all possible.

30 8) A more esthetic design for

(MacDonald)

1 Stoney Creek and the long viaduct.

2
3 In closing I do not want to shock
4 the Panel but despite the volumes of words most
5 of it is a collection of the necessary technical
6 data any major project requires. The concerns
7 I expressed to you last year I feel are still
8 with us. Any possible success for reclamation
9 rests with these recommendations. I personally
10 feel your final report should await decisions
11 on these matters. Thank you very much.

12 THE CHAIRMAN: Thank you,
13 Mr. MacDonald. We will now take our coffee
14 break and come back and commence some questions
15 on these presentations.

16 --Brief adjournment.

17
18 ---UPON RESUMING:

19 THE CHAIRMAN: I should mention
20 that I believe that we did not put out Mr.
21 MacDonald's C. V. and he was too modest to mention
22 it himself, but he is the Chief Engineer with the
23 National Capital Commission at the present time.
24 Anybody who wants any more details, they can talk
25 with Mr. MacDonald directly.

26 I would like to start then with
27 the presentation by Parks Canada and Doctor
28 Leeson.

1 (Leeson)

2 DR. BRUCE LEESON, (Parks Canada):

3 Mr. Chairman, this is less of a
4 presentation than it is just a comment, and it is
5 directed specifically to the subject to terrain
6 impact in our submission, which I presented
7 Wednesday night.
8

9 We talked about our concern for
10 the large amount of terrain impact that is proposed
11 in this project and I want to advise you that
12 since Christmas we have spent a lot of time with
13 C. P. Rail and their consultants examining the
14 various generations of grade profiles that
15 were produced, and initially expressed our alarm
16 about the wide clearings and the large fills
17 and in numerous instances, C. P. Rail was able
18 to reduce those fills and cuts. However, as you
19 can see from the drawings there are substantial
20 ones remaining.

21 We do not have any further
22 in-house technical ability to examine what is
23 being proposed and for that reason we ask the
24 Panel's special attention and particularly through
25 your technical experts to comment about that
26 and to examine C. P. Rail's proposals to see if
27 there is a better alternative. We see that
28 they are doing that and we are hoping that you
29 will continue to be diligent to sure that the
30 best is identified.

1 (Leeson)

2 In that regard when the Panel's
3 work is all finished and whatever is approved
4 is approved, then we, that is Parks Canada, will
5 be faced with the need to examine the site specific
6 proposals, and once again we will find ourselves
7 short of technical ability to evaluate whether
8 what is being proposed is the best or not, and
9 I would ask the Panel's consideration of what we
10 ought to do in this circumstance and perhaps your
11 comments about what is done in other projects
12 where you face situations of a similar magnitude,
13 and whether or not the Panel has the inclination,
14 wherewithall or the mandate to continue to provide
15 Parks Canada with some kind of assistance so that
16 we can look after ourselves in future weeks.

17 Thank you.

18 THE CHAIRMAN: Okay, that is a good
19 point to bring up. I think now what I might
20 do is ask the Panel if they have any questions
21 that they would like to ask on these presentations,
22 and I will give both technical experts and C. P.
23 an opportunity to come into some.

24 Just for the record though, so we
25 get this down somewhere before we finish these
26 hearings, can we get a confirmation on what the
27 exact right-of-way width is. Three hundred and
28 seventy-eight feet I think was mentioned in the
29 Red Book. I heard another figure given just
30

1
2 here. I had a conversation with one of your
3 employees from C. P. Rail, one of your experts,
4 that mentioned I think 316, and I think we are
5 reasonably agreed on the width of the clearing
6 average - between 156 and 158, but just for the
7 record if you can give me those figures so we can
8 report it to the Minister.

9 MR. FOX: Unfortunately, Mr.
10 Chairman, and I should have made note of this
11 when we started, there are one or two typographical
12 errors in that Red Book and one of them happens
13 to be the number of acres. The figure is 316
14 acres.

15 Now to clarify that further
16 that includes approximately 20 acres of land where
17 the new right-of-way almost abuts the existing
18 right-of-way, and we felt that we should include
19 that in the land to be taken from Parks. So it
20 will not be worked on. It will just be left as
21 it is today, but for the ease of preparing legal
22 documents for land purposes, we felt we should take
23 those narrow strips that were left between the
24 two right-of-ways and we included that, and
25 that amounts to approximately 20 acres.

26 THE CHAIRMAN: And the other
27 figure is at 156 or 158 or can we do a deal at
28 a 157?

29 MR. FOX: That number is correct
30

1 in the book. That is the number.

2 THE CHAIRMAN: Thank you. Bill
3 Ross?

4 MR. FOX: Whatever it is, it is
5 right in the book!

6 DR. ROSS: I guess my first
7 question is to C. P. Rail, which I think I am
8 reiterating a query which was made a couple of
9 times. The most important issue is what are
10 the remaining prospects for reducing the right-of-
11 way. In any case, whether it is 100 meters or
12 90 meters, it is a lot more than was approved
13 and so on in the interim fashion by the C.T.C.
14 That is quite a wide right-of-way and I am
15 wondering whether the continuing prospects
16 for reducing that with retaining walls, with
17 mechanisms such as extending the viaduct for
18 longer stretches or things of that sort.

19 MR. FOX: Well, you know you
20 are getting into a realm and I think Mr. MacDonald
21 alluded to it. You have got to look at costs
22 and for the sake of let us say -- we took a
23 rough guess at it and I think you may be looking at
24 probably 10 acres of land that we could probably
25 cut back on on the downslope side by the use of
26 retaining walls, and we took a look at one in
27 particular, and we can give you an example of it
28 if you wish to go through the thrash -- we took
29 a look at one of the worse ones which is in the
30

PM-D-11

70

1 vicinity of Raspberry Creek and very arbitrarily
2 said we will put in a retaining wall there of
3 approximately 40 feet in height and it would have
4 to be 600 feet long, and what would be the
5 ramifications of building a wall of that size at
6 that particular location, and it goes something
7 like this: we would save 1.7 acres, I believe
8 it was, of land with that type of wall with the
9 slopes we are now proposing. The cost per
10 acre of saving would be something like \$2.4
11 million. In the overall picture if we use the
12 retaining wall, and this is very rough because we have
13 not had much time to sit down and do a complete
14 review of it, but just a broad brush figure --
15 the increase in cost if we use that type of a process
16 on all the downhill slopes, you are looking at
17 somewhere between 18 and 25 million dollars
18 additional in cost.

19
20 More importantly if you go in to
21 build these mammoth retaining walls like we
22 are talking about, and they are large, you would
23 literally tie up the entire right-of-way with
24 a crew building nothing but retaining walls and
25 you would be doing no dirt work. You have to
26 maintain an access to them, and if you have to
27 go in there, and I am sure that Mr. MacDonald will
28 agree with me, and cut back into the slope sufficient
29 distance to get a proper foundation. you have
30 got excess material that comes out that you have

1
2 got to dispose of, and when you are doing that
3 you have got such a big cut at the base you cannot
4 get any earth equipment around the thing. You
5 have got additional crews in there. As I mentioned
6 once before I believe at one of the hearings,
7 Revelstoke, we do not have proper granular material
8 in that country to use as back fill for filtering
9 and drainage. All this would have to be trucked
10 in out of the Park. You are looking at, I would
11 guess, just a rough guess, on the cost of your
12 granular material, proper granular material of
13 something like \$20.00 a yard to haul it in there
14 by truck.

15
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30

E-1

1 So when you put the whole thing
2 together, you add, I would say, about a third
3 to your cost, total cost and it just becomes
4 absolutely horrendous.

5 Now, having said all that, having
6 said all that, what we have been looking at all
7 through this piece is the visual impact. That is
8 what has been impressed on C.P. Rail from day one,
9 is visual impact. The downhill slopes cannot be
10 seen except in one or two locations. I cannot
11 reclaim a retaining wall; I cannot grow anything on
12 a retaining wall, it will not grow. So, you know,
13 you will live with a retaining wall.

14 Having said all that, why would I
15 have to go and spend an extra 18 to \$25 million
16 on the downslope -- I am just talking downslope now,
17 not upstream, just downslope. Why would we have to
18 spend money like that when we do not improve the
19 visual impact one iota. Now, that is what we have
20 got to address ourselves to.

21 Now, if you would like to have an
22 example of what we have gone through, we can give
23 you that example.

24 THE CHAIRMAN: Before we get too
25 deep into that discussion, could I ask, your right-
26 of-way is based on a square going from point to point,
27 or a rectangle, if you like. Presumably if you
28 went along like a sawtooth fashion following the
29 width of your clearing you could reduce the width
30

E-2

1 of your official legal right-of-way considerably
2 down almost to the point of clearing if you wanted to
3 or something like that.

4 MR. FOX: Yes, you can.

5 THE CHAIRMAN: It is just, I guess,
6 difficult for the legal surveyors to go and do some-
7 thing like that.

8 MR. FOX: Well, you know, can you
9 imagine the description.

10 MR. TENCH: Can I ask what your
11 estimated cost, Mr. Fox, is of the surface route from
12 00 up to the east end of the short tunnel so that
13 we can get a handle on some of these figures that
14 you are giving to us.

15 MR. FOX: It is of the order of
16 \$65 million and that is not a precise figure.

17 DR. ROSS: I have a couple of other
18 points but I think I would leave them until tomorrow
19 because they deal more with visual impact which I
20 think we agree is more important, and if we are
21 going to deal with that tomorrow, then I will put
22 them off for now.

23
24 I have two other brief points, one
25 of which I guess is to Parks. We discussed I guess
26 the day before yesterday the question of off right-
27 of-way drainage and we saw a number of presentations
28 today, Dr. Leeson, with the kinds of drainage that
29 is being proposed.

30 Now, is that the sort of material

E-3

1 that you were concerned with or is that the sort
2 of material that you find acceptable, and I guess
3 what is your view on the sort of drainage mechanisms
4 and fluming mechanisms that were proposed here today?

5 DR. LEESON: If the fluming that
6 is being described today is of the same sort that
7 was installed in the wet bog area last fall, that is
8 acceptable. That was put in with a minimum of
9 impact, very few trees cut, put in by hand labour
10 and helicopters, and if that is what they are talking
11 about, that is pretty good.

12 The sort of undertaking that
13 we do not like is what was necessary at the top of
14 the Big Cut at Lake Louise where heavy machinery,
15 bulldozers were taken in and ditches approximately
16 50 feet wide in a herringbone fashion were constructed.
17 That is what was necessary there. That is what we
18 do not want.

19 But if, in reference to fluming,
20 they are talking about the same sort of thing that
21 they have done already, we would find that to be
22 quite acceptable and I would seek clarification of
23 exactly what they are talking about.

24 DR. ROSS: Mr. Fox.

25 MR. FOX: What we are thinking of
26 is exactly what you described, Dr. Leeson, but in
27 any event, when the final plan is put together for
28 those particular areas, we will see that you have
29 a look at them before anything is done or wherever it
30

E04

1 is you wish to look at them.

2 MR. TENCH: Mr. Fox, Mr.

3 MacDonald had about six points in summary of items
4 that he raised, and Mr. Chairman, is this a sensible
5 time to ask for some response from C.P. on these
6 points?

7 THE CHAIRMAN: If they can respond
8 to them. If not, we could hold it until tonight.
9 Do you want the points repeated one by one?

10 MR. FOX: I am not sure we got
11 them all down, but we had site specific construction
12 scheduling, that was one, I believe.

13 THE CHAIRMAN: Do you want to deal
14 with that one?

15 MR. FOX: Yes. I am inclined to
16 agree with Mr. MacDonald on that. That really is
17 a contractual documentation thing that you have to
18 do and I think if you looked at our schedule of how
19 we handle quantities, you can see pretty well that
20 that is the sort of thing we are going to do.

21 So I certainly agree with that number
22 one.

23 Now, he is talking about two to
24 one slopes. I agree. I would love to have two to
25 one slopes, but I do not know if I can get them.
26 I would love to have it. It would stop a lot of
27 nonsense. We would be able to do the reclamation
28 the way it is supposed to be done, but I cannot say
29 that I can -- I can put them in there but Parks is
30

E-5

1 not going to like it one little bit.

2 THE CHAIRMAN: Well, just a second
3 on that one. You are proposing reclamation plans,
4 and I am assuming you considered those will be
5 successful reclamation plans, otherwise I do not
6 know why you are proposing, and I think that was
7 Mr. MacDonald's point.

8 MR. FOX: That is right. Well, I
9 can put it to you this way. My expert claims that
10 he can do a job in one and a half to one slopes up
11 to a point, and some of the slopes, as Mr. MacDonald
12 mentioned, go back at one and three-quarters to one
13 on the higher ones and some at two to one already.
14 They were put in there particularly for reclamation.

15 Now, if my expert says he can do
16 it, he had better well do it.

17 THE CHAIRMAN: I guess we will hear
18 tomorrow from the reclamation people as to whether
19 that is feasible or not.

20 MR. MacDONALD: Mr. Fox, if I could
21 add one point there. In regard to the two to one
22 and the reference to the possible use of retaining
23 walls, it does not necessarily mean, for example,
24 I suppose what I had in mind is the possibility
25 of some areas that are going to show above the tree
26 lines on the cuts, for example.

27 MR. FOX: You are talking the
28 upslope, uphill ones now.

29 MR. MacDONALD: Yes. If there is
30

E- 6

1 some possibility, for example, to put a small
2 retaining wall and for a short area you get two to
3 one so that you can get planting on, that gets you
4 below that tree line.

5 Now, at the bottom of the retaining
6 wall you could be going back to one and a half
7 to one or 1.75 to one and onward down. What I am
8 trying to say, is, it is very -- as I say, I wrote
9 that at two o'clock in the morning and you cannot
10 sort of break it down into all the various segments,
11 but what I am getting at is it is not cut in stone,
12 you know. You try to find is there some area in
13 which you could use the retaining walls up on the
14 upcuts and actually enable you to revegetate some
15 of these areas that are going to show above the
16 tree line.

17 MR. FOX: Well, most of the
18 upslope are ---

19 MR. MacDONALD: Are rock,
20 unfortunately.

21 MR. FOX: Yes. We do have a lot
22 of retaining walls up there and there is an amount
23 of rock up there too, and what we have really done
24 up there, Mr. MacDonald, in terms of the design of
25 the alignment and the location of the alignment was
26 we tried to hold it away from the uphill side as
27 much as possible, knowing that that is the part
28 that was going to be most visual. So that has,
29 of course, increased the size of our downslope cuts or
30

E-7

1 at least our downhill fills -- not cuts, fills.

2 MR. MacDONALD: As I say, I have
3 mentioned that there were quite a few 1.75 to one
4 fills, as I say, in the Griffith slide, for example,
5 and unfortunately the darn plan shows the ground
6 line going practically out flat at that point, so
7 that actually two to one there could be put and then
8 all you are talking is fill.

9 MR. FOX: Well, I think we have
10 two to one on all the slide areas and that was
11 done very deliberately.

12 MR. MacDONALD: It must have been
13 changed then because Griffith is still shown at 1.75
14 to one.

15 THE CHAIRMAN: Hold on a minute here.
16 We are going to lose the discussion altogether.

17 I think we were asking Mr. Fox to
18 reply to the various points and then maybe when you
19 have replied to the points we can come back on them,
20 otherwise I am going to lose the discussion completely.

21 MR. FOX: I think another point
22 that Mr. MacDonald raised, or we have anyway, is
23 the revegetation as soon as the slopes have been
24 completed. I agree with you there, too, and that
25 is what we propose to do. I think if you looked at
26 our scheduling diagram, it indicates that.

27 I think the next thing was your
28 scheduling of actual construction. I think you made
29 some remarks about short working season, and we should
30

E-8

1 work in the best part of the season.

2 MR. MacDONALD: Again, that was
3 an argument supporting the site specific generally.

4 MR. FOX: Right. Well, the work
5 season in that country there is somewhat longer
6 than you have alluded to, Mr. MacDonald, and I
7 appreciate that coming from Ottawa you perhaps would
8 not have all the facts.

9 You can generally go in there some-
10 where between June 1 and June 15 and you can work
11 through very safely to about the end of October,
12 sometimes later than that.

13 MR. MacDONALD: Just one moment now,
14 on the fill?

15 MR. FOX: I am sorry?

16 MR. MacDONALD: On the fill?

17 MR. FOX: Yes, you have good
18 weather all the way through there.

19 MR. MacDONALD: Then you go
20 through the complete winter with an exposed ---

21 MR. FOX: Well, you are bound to
22 get some of that. But you know, the best you can,
23 you will cover the revegetation and what has been
24 completed. If it is not completed, as you well know
25 in the construction game, is it is rather tough.

26 Anyway, it is something that has
27 to be watched and you do the best you can. Now, a
28 lot of these fills will be done progressively too,
29 hopefully.
30

E-9

1 One other thing I wanted to say and
2 I did mention to you this when I was having coffee,
3 the elevations up there are not quite as bad as
4 one would have you believe. The elevation at
5 Rogers, for instance, is 2640 feet above sea level,
6 and at the east portal of the short tunnel it is
7 3200 feet above sea level. Calgary is 3500 feet,
8 so you can get sort of relative values, and that is
9 good growing weather usually up there, which is
10 in our favour hopefully.

11 Benching. We stayed away from
12 benching. We have done it in the past and it has
13 only been moderately successful, if you could even
14 call it that. For that reason we did not, in this
15 case, go to benching at all. We did a line
16 diversion some years ago down near the Cranbrook
17 area where we put in extensive benching and it
18 really turned out to be very much of a disaster.
19 We wished afterwards we had never gone near it.

20 So we have had experience in it and
21 we really do not see that it gives you much value,
22 if any at all. Sometimes it gives you no value at
23 all, it is worse. So for that reason we stayed away
24 from it.

25 Alignment of Mountain Creek. That
26 is a toughy because we are coming in there on a
27 six degree curve, going across the river and
28 then coming off at another six, and the constraint
29 there is there is a campground at that location.
30

E-10

1 MR. MacDONALD: The one on the
2 other side is a five.

3 MR. FOX: I am sorry?

4 MR. MacDONALD: You come in on a
5 six and leave on a five.

6 MR. FOX: Well, they are just
7 about the same. Six and five, I stand corrected.

8 Anyway, to straighten it out and
9 maintain your alignment further east, which we
10 are pretty well tied down to for various other
11 constraints would mean that we cut right through
12 the top part of the existing campground, where I
13 believe they have some sort of a theatre set up there.
14 We have deliberately stayed away from that because
15 of Parks' concern about what we would be doing.

16 In addition to that we tried to
17 get it into a location so we could get a berm so
18 it would cut down the sound going through there.
19 So there are constraints.

20 MR. MacDONALD: It is a case of
21 trade offs.

22 MR. FOX: That is right, and I
23 would love to have a nice square crossing, too, as
24 I am sure everybody would.

25 THE CHAIRMAN: George Tench, you
26 have a question.

27 MR. TENCH: Bless you for getting
28 me back on the track again.

29 Parks, you heard the discussion
30

E-11

1 between the two experts here which would leave you
2 with quite a lot of blank faces as far as I am
3 understanding the scene. Is this news to you? Were
4 you anticipating this? In other words, surfaces
5 that are possibly visible that according to Mr.
6 MacDonald, it does not appear to be feasible to try
7 to revegetate.

8 DR. LEESON: No, that is what we
9 have been saying all along, that we think the
10 reclamation is overly optimistic, that it is going
11 to look like heck. There is going to be a terrific
12 impact, and when it gets there, everybody is going
13 to be surprised. They are going to say, boy,
14 that is a terrific impact on the park.

15 THE CHAIRMAN: Were there any more
16 points from Mr. MacDonald you had to deal with?

17 MR. TENCH: Yes, there was one
18 here. It was

19 suggested that some of your bridge design was
20 perhaps rather antiquated and maybe you could do
21 yourselves a little better.

22 MR. FOX: Well, I guess if
23 you are one engineer you will say my design is the
24 greatest, and if you are another engineer you will
25 say it is no damn good, and that is the way life
26 goes around. Is that not right, Mr. MacDonald?

27 Anyway, what we are looking at up
28 there, we are looking at a possibility of a precast
29
30

E-12

1 type concrete structure if that is at all feasible.
2 We have some problems in our mind about the weight
3 of that type of a structure.

4 Another structure that probably will
5 be put in there is going to be a steel type trestle
6 with deck type girders on top. Now, they are not
7 all that bad. We have one down at Lethbridge. I
8 do not know if you have ever seen it, Mr. MacDonald.
9 It is 6,000-odd feet long; it is 340-odd feet high.
10 It is rather a striking structure. It stands out
11 in the skyline very nicely. In this case of course
12 you will not be using steel that you have to paint.
13 You will use the corten type steel which I
14 consider to be a nice maroon colour after a year
15 or two. That may not appeal to some people, but
16 it is a nice looking colour.

17 For instance, there is the one
18 we put over the highway at Lake Louise. That is the
19 type of structure I am thinking of, that colour
20 anyway.

21 MR. MacDONALD: Just do not use
22 concrete abutments, they stain them.

23 MR. FOX: I am sorry?
24

25 MR. MacDONALD: Do not use concrete
26 piers or abutments, they stain them.

27 MR. FOX: Well, you will get some
28 staining at times, that is right, but hopefully if
29 we put a trestle up, that is exactly what it will
30 be. It will all be corten right down to the foundation.

E-13

1 The other structures are basically
2 a railway type structure that we use quite
3 extensively throughout the railway, and I think for
4 the most part if not -- I guess one exception would
5 be Alder Creek, they are all deck type structures
6 and rather clean lines. Now, I know you can dress
7 up bridges to whatever extent, but ---

8 MR. MacDONALD: You are talking
9 the deck plate girder?

10 MR. FOX: That is right, with a
11 ballast type deck on top of it. No open deck or
12 anything like that.

13 Anyway I hear what you say and I will
14 scratch the bridge boys a little bit and see if we
15 cannot do some little fancywork, but I think Mike
16 McKnight is right, you are not going to see that
17 big trestle at all; that will be well hidden.

18 THE CHAIRMAN: I think, George,
19 did you have another question?

20 MR. TENCH: That was not my
21 question. The big trestle is going to be entirely
22 out of sight of the highway?

23 MR. FOX: You will never see it
24 from the highway, not unless the guy is on a boom
25 type ladder or something.

26 THE CHAIRMAN: To deal with this
27 question of the retaining walls, I realize you
28 mentioned a question of task, but there was, in a
29 presentation by Mr. Hurwitz or Dr. Adam, reference
30

E-14

1 on page 8 to what they considered to be a problem
2 area, Station 284, and I think it is to Station 384
3 although you may have said 284 in the record, I think
4 it is to 384.

5 They are talking about downslope
6 retaining walls. Mr. MacDonald, I believe, was talking
7 about upslope retaining walls. Now, I would like
8 to ask a question to Mr. MacDonald and to C.P. as
9 to whether the use of retaining walls in that area
10 is feasible and whether it is a question of cost
11 being the problem in that particular area, that it
12 makes the cost per acre very, very high.

13 MR. FOX: We are talking the
14 downslope ones?

15 THE CHAIRMAN: That is what I
16 understand since it is fills, they would be down-
17 slope.

18 MR. FOX: My remarks that I made
19 initially covered the downslope ones. I was under
20 the impression that Mr. MacDonald was talking
21 downslope walls.

22 MR. MacDONALD: You were right in
23 the sense that when I was dealing with the right-
24 of-way you would, in all likelihood, use some
25 downslope and upslope to have any success in
26 reducing it.

27 MR. FOX: But that is what you
28 would have to do.

29 MR. MacDONALD: When you get into
30

E-15 1 reclamation, of course, I was really more concerned
2 with the upslope which is the visible ---

3 MR. FOX: Right.

4 THE CHAIRMAN: I believe in that
5 particular area that is pretty visible, in that
6 294 to 384. Maybe, Mr. MacDonald, would you see
7 retaining walls being feasible? That is one question.
8 The second part of the question is economics on them.

9 MR. MacDONALD: Well, there is no
10 question, you can build retaining walls. It is a
11 case, you know, the size, how much do you want to
12 move -- I presume, is it for the right-of-way reason,
13 Larry, the reason for the retaining wall that
14 you are talking about right now.

15 MR. HURWITZ: Basically, yes.
16 It was in reading the description, pages 31 to 36,
17 retaining walls were considered and apparently
18 rejected. I thought that it would be a possibility
19 to reduce some right-of-way requirements at
20 certain fills, not necessarily all fills in that
21 section. Mr. Fox said earlier that you cannot see
22 them anyway, which I was not readily aware of.
23 You know, if you cannot see them, maybe the fill is
24 satisfactory. On the other hand, saving 100 feet
25 of trees in clearing seems to be a reasonable thing
26 to do, but this economic question is one that has
27 to be considered too.

28 THE CHAIRMAN: I think that is a
29 pretty visible area just looking at my version of
30

1 what is around the walls here, and I guess the
2 question to Mr. MacDonald, or the answer is you
3 can put them downhill as much as you can put them
4 uphill, and your idea of going to two to one and
5 then benching down with a retaining wall applies.

6 MR. MacDONALD: I think it is
7 important to realize, you know, our geotechnical
8 experts mentioned before that in most of the cases
9 the material is pretty sound material and you can
10 bench into it and you can put a retaining wall, as
11 Mr. Fox said. It is a case of height and cost
12 and results.

13 For example, if it is visual, again,
14 I think you have been using a green coloured one
15 I think at the east portal, if I recall.

16 MR. FOX: We have got green there,
17 a pretty pale sickly green and we cannot put any
18 more colour in it or we ruin the concrete.

19 MR. MacDONALD: I do not know how
20 Parks Canada feel. What does that look like through
21 the trees? You know, in plain English, does that
22 look better than looking at a fill? These are the
23 things that you are looking at.

24 MR. FOX: Well, let me just get some-
25 thing clarified. What fills are we talking about
26 so I can get a handle on it.

27 THE CHAIRMAN: Page 8, presentation
28 by I.D. Systems, last five lines.

29 MR. FOX: Well, the fills, and I
30

1 will start at Station 304, right through to
2 360, you cannot see the bottom slopes. There is a
3 little bit of an opening just beyond 360 in the wet
4 slide area, and I would not put a retaining wall in
5 there because the foundations are not good. You can
6 see a little bit of fill just west of 364. Without
7 looking at the actual cross-sections, I do know
8 whether a 30 or 40 foot high fill would bring you
9 up to the top of those trees or not.
10

11 THE CHAIRMAN: Particularly
12 between 360 and 380 in there, there is an area.

13 MR. FOX: Three-sixty to 380, you
14 do not see any of them in there.

15 The first one you see is almost
16 Station 400 and there is another one at about 407.

17 THE CHAIRMAN: Then those must be
18 cuts rather than fills in that area.

19 MR. FOX: Yes.

20 DR. ROSS: I wonder, Mr. Hurwitz,
21 if there are other questions in your submission which
22 we have missed which we want to go back on?

23 MR. HURWITZ: The question of why
24 the right-of-way and width cleared, are my numbers
25 right there that I generated on page 8?

26 MR. FOX: Well, the total acres
27 involved that will be taken in terms of property is
28 316.

29 MR. HURWITZ: So that is reduced
30 from the 371?

1 MR. FOX: That is right.

2 MR. HURWITZ: Then the right-of-
3 way figure would go down. The clearing figure, on
4 average, 156. I recognize that it is variable.

5 MR. KLASSEN: The book says inside
6 the park for clearing 158.

7 MR. HURWITZ: Yes, I am talking
8 width, though, Meryl. I am not talking area.

9 THE CHAIRMAN: I think the question
10 is the right-of-way being doubled to clear the width
11 is because it is going point to point. That is what
12 we were discussing earlier on, rather than following
13 the cleared area. Was that the point you were trying
14 to elaborate on?

15 MR. FOX: Mr. Chairman, I have
16 a hard time in following. I appreciate that we
17 are taking somewhat more acreage based on what was
18 shown on the board plan, and the board plan shows
19 we required a minimum width -- or it did not show
20 a minimum. It showed a width of 200 feet, 100 feet
21 each side of the center line.

22 As I recall and without going into
23 the proceedings, but as I recall last year, we had
24 a rather lengthy discussion on the right-of-way, and
25 it was indicated, as I recall, to this Panel that
26 ina number of locations we would have to take more
27 right-of-way than shown on that plan because of what
28 the fills and cuts would do to us. I think I am
29 right when I say that.
30

E

1 THE CHAIRMAN: I do not ever remember
2 200 feet being on the record in these meetings. I
3 have looked back at them and I think the only thing
4 we talked about is what became apparent was the
5 initial right-of-way and having to go beyond that.

6 MR. FOX: Well, I think if you
7 look into it closer, you will find out, I think you
8 were talking about one thing and we were talking
9 about something else because I distinctly remember
10 Mr. Wakeley making the point that we would require
11 more right-of-way in the final analysis than the
12 200 feet shown on that board plan.

13 THE CHAIRMAN: If you can show me
14 the record, I would be very pleased with that
15 information.

16 MR. FOX: In any event, regardless of
17 what was said, and we did have a discussion on it,
18 the fact remains that if you are going to build in
19 a territory such as we are building in, you cannot
20 live within a band, be it 200 feet all the way through
21 it. It is just a physical impossibility, and having
22 said all that, 316 acres of land and as I indicated
23 there is about 20 acres of that to make up the
24 difference between the two property lines where they
25 come close together, you know, you are talking about
26 a pretty small farm, to put it in its proper context.

27 DR. ROSS: You may be looking at
28 a small farm, but you are also generating, I think
29 it is generally agreed, a potentially significant
30

1 impact on the park.

2 MR. FOX: No, I do not agree, Dr.
3 Ross, because we have done it on the downhill side.

4 DR. ROSS: Well, several people
5 have indicated that they believe this has potentially
6 significant visual impact in the Park and I think
7 we may be heading to the point where we have to
8 deal with the visual impact and for that reason I
9 am inclined to wait until tomorrow, but I think
10 what is crucial here is your ability to undertake
11 a good reclamation scheme which will mitigate this
12 visual impact because ---

13 MR. FOX: I agree with you.

14 DR. ROSS: I think that is crucial
15 because there are areas which unmitigated would
16 clearly be a serious visual impact and I think what
17 we are trying to deal with is some mechanism for
18 reducing that impact which we I believe now all agree
19 is significant.

20 MR. TENCH: Is this right-of-way
21 acreage something that Parks have realized all along
22 or are these figures much larger than they
23 anticipated?

24 MR. GALLACHER: In order to give
25 you an answer to that, I would have to check with
26 the property people, the realty services people
27 because they have been working on this and I think
28 it is somewhere around what we expected from the
29 preliminary discussions I had with them.
30

1 THE CHAIRMAN: Bill Ross.

2 DR. ROSS: The Cedar Creek diversion,
3 Parks, is that current plan, which I guess is the
4 east diversion now, is that looking reasonable? I
5 understand you had some objections to the west
6 diversion plan which existed a week ago?

7 DR. LEESON: We objected to the
8 west diversion plan because it affected wet lands
9 in the Beaver Valley and Mr. Fox's beloved beaver
10 would be impacted.

11 So we asked why can it not go to
12 the east, approximately where it is now. That has
13 been investigated and regretably there is a large
14 amount of terrain impact with that too. It has
15 just recently been shown to us.

16 So whether one is going to be a lot
17 better than the other, I do not know. We now have
18 to have a detailed examination of it within the Design
19 Committees.

20 DR. ROSS: That was what I was
21 essentially asking, how you compared the terrain
22 impact of the east diversion with the benefit for
23 the wet lands below?

24 DR. LEESON: We have not done that
25 yet, Dr. Ross, but we will do that in Committee.

26 While I am up here, can I ask a
27 question?

28 THE CHAIRMAN: Sure.

29 DR. LEESON: On page 10 of Mr.
30

1 Hurwitz's and Dr. Adam's presentation with respect to
2 hydrology, they ask the question about the dyking,
3 particularly Mountain Creek as far as we are concerned,
4 and I would like to have that question answered as
5 to whether or not it is possible to do it some other
6 way, and also clarification as to the material source.

7 THE CHAIRMAN: I believe Mr.
8 MacDonald had some questions about dyking as well,
9 or training walls as well, which I am not sure we
10 have had answered so perhaps you could deal with
11 that in generality?

12 MR. FOX: Well, the dyking, I do
13 not have my plan in front of me, as I recall is not
14 in the river at all. It is on the river bank in
15 the dry, and it consists really of heavy stone type
16 wall which will deflect the water away from back
17 of the abutment. That is all it is. It is not in the
18 river at all, and it is very similar to existing
19 training walls that already exist in the Park.

20 If you would like to have the name
21 of one that you would like to go and look at, there
22 is one on the Beaver River leading over to the
23 Parks gravel pits, very, very similar to that one
24 right there. So far as where the material comes from,
25 all it has to be is what we call one man stone, and
26 we will probably be making that out of some of the
27 stonework -- I say probably. We will be making it
28 out of the stonework as we go along the route and
29 haul it up there and have it placed. So it is not
30

1 going to affect the bed of your stream or any part
2 of your stream. All it does in terms of times of
3 high water, when the water comes down there is a bit
4 of a bend there and to deflect the water away from
5 the side of the abutment we will put a wall in
6 there and make sure the water does not get in
7 behind the abutment and cause a washout. That is
8 all it is there for. It is strictly a safety
9 thing. It will not be in the river at all.

10 THE CHAIRMAN: Mr. MacDonald, do
11 you have any comments?

12 MR. MacDONALD: Yes, is it possible
13 to do it with native stone, native to the stream
14 itself?

15 MR. FOX: If they will let me
16 take the stone out of the river, Mr. MacDonald, I
17 will be glad to take it from that source.

18 THE CHAIRMAN: Parks, I think I
19 know the answer, but do you want to tell us whether
20 you would allow that to do?

21 DR. LEESON: Is this a Gabion
22 type of structure?

23 MR. FOX: No, it is just stone that
24 is piled up in a wall about yeh high.

25 DR. LEESON: Sort of a drywall type
26 of ---

27 MR. FOX: That is correct.

28 DR. LEESON: Well, I do not think
29 we would be too keen on having it taken out of the
30

1 river in the method that it would be necessary to do
2 so.

3 THE CHAIRMAN: Fair enough.
4 Are there at this time any questions from members
5 of the audience public concerning any of these
6 presentations?

7 Perhaps Dr. Adam, Dr. Hurwitz, have
8 you got any points that you would like to raise
9 concerning any of these presentations?

10 DR. ADAM: I think the only point
11 I would make is to make sure people realize that there
12 is a connection between the concentrations I mentioned
13 and the concerns that Mr. MacDonald expressed with
14 regard to erosion. There is a very real connection
15 there that can only achieve those concentrations
16 in a stream if you have the protection to stop
17 the erosion or sediment traps and so on, so there
18 is an unlying concern to that requirement that I ---
19

20 THE CHAIRMAN: You are suggesting
21 a quantitative standard to deal with a perceived
22 problem?

23 DR. ADAM: That is right.
24
25
26
27
28
29
30

PM-F-1

1 THE CHAIRMAN: The other method
2 is, of course, the scheduling which Mr. MacDonald
3 is suggesting.

4 C. P. do you have some points
5 you want to raise at this time on this topic?

6 MR. FOX: Perhaps I can come to
7 it, Mr. Chairman. I would like to make one or
8 two remarks on the I. D. Systems Paper. On page
9 5, it indicated that we were conservative in our
10 design for drainage structures. I agree that
11 we are conservative. I do not know whether I
12 said it at this hearing or not but the experience
13 that I have had in mountain streams is that
14 you do not play games with a mountain stream;
15 you put lots of opening in there because you are
16 going to need it, and if you cut corners you have
17 a big bill to pay. I agree with what you say and
18 we are over conservative for that particular
19 reason.
20

21 Visual monitoring that is -- we
22 are going to go a little bit further than that.
23 We are setting up a monitoring system to actually
24 test the waters both upstream and downstream.
25 I do not know whether that has been covered yet
26 or not. Doctor Foster will be covering that,
27 and the total solid suspension, he should be
28 covering that at the same time. That is on page
29 7.

30 Another on page 7 about the concerns

PM-F-2

1 on whether this Crow Rate business delays the
2 construction. I cannot tell you when it is going
3 to be passed. I do not control Parliament, but
4 there is an agreement in place between Parks
5 Canada and C.P. Rail as what will be done in the
6 event that that agreement, or at least that Rate
7 is not fixed and we do not go ahead with the project.
8 There is an agreement in effect that takes care
9 of that. That was signed last year.

10 DR. ROSS: Mr. Fox, could tell
11 us roughly what that agreement says?

12 MR. FOX: What it says is that
13 if we do not start before July of 1984 we have
14 to go in there and reclaim the whole thing;
15 reclaim it in the sense that we do the complete
16 reclamation work.

17 Now to come back to your question
18 and perhaps you could repeat it for me to make
19 sure I understand, Doctor Adam, that you were
20 talking about whatever with the Chairman?

21 DOCTOR ADAM: It is simply that
22 in order to meet 500 miligram per litre concentration
23 downstream, you are going to have fair control
24 of erosion on slopes and so on, and so it is
25 just another way of coming at the concern that
26 Mr. MacDonald expressed. Just to tie it all
27 together it seems to me that it does not make
28 much sense to treat your waste water from tunnels
29 and so to bring it down to 60 and put it into a
30

PM-F-3

1 stream that has a suspended solids concentration
2 higher than that. It is just that it all --
3 just to be logical, I think you have to be
4 talking at least in the same order of concentrations.

5 MR. FOX: Okay, I am not an expert
6 in that particular field myself, and I would like
7 to defer that answer to Doctor Foster, who will
8 be giving a talk on that thing tomorrow, and
9 could we keep that in abeyance until that time,
10 or you can have an answer now if you would like
11 to bring him forward.

12 THE CHAIRMAN: Well, maybe we
13 could deal with that one now if it is possible
14 to do so.

15 MR. TIM HOLLIBAUGH (MacLaren
16 Plansearch): Okay, the tunnel effluent will
17 not be discharging into any of the streams crossing
18 the right-of-way. They will be discharging into
19 the Illecillewaet River or into the Beaver
20 River, which are removed by some distance from
21 the right-of-way. Now it is true that the streams
22 which are draining the right-of-way eventually
23 wind up in the Beaver and the Illecillewaet
24 Rivers, or, well, the Beaver River rather, and
25 they will be monitored.

26 DOCTOR ADAM: I realize that but
27 it is just a matter of principle of why would
28 you treat water to bring it down to that concentration
29 coming from a tunnel and yet you let it run off
30

PM-F-4

1 slopes into streams and create much higher
2 concentrations.

3 MR. HOLLIBAUGH: No one has
4 proposed to let it run off the slopes and create
5 much higher concentrations.

6 DOCTOR ADAM: Right, and that
7 is the suggestion, and Mr. Fox has assured me that
8 that is in the plan.

9 MR. HOLLIBAUGH: Right.

10 DOCTOR ADAM: Right, but it is
11 just that the two to me are tied together in that
12 there is no point on one hand treating it to
13 bring it down to one level and at the other --
14 on the other hand not having any criteria.
15 That is simply my point.

16 MR. FOX: I see what you are
17 getting at now. What Doctor Adam is saying is
18 if we treat the tunnel effluent to a certain level,
19 we should treat all other streams either to the
20 same degree and monitor to see if we have that --
21 I think that is what you are saying.

22 DOCTOR ADAM: That is right.

23 MR. HOLLIBAUGH: Which I think is
24 what we plan on doing anyway.

25 MR. FOX: Exactly, exactly.

26 THE CHAIRMAN: Do you have any
27 more points Mr. Fox that you want to cover at this
28 time?
29

30 MR. FOX: I do not think so. Thanks.

PM-F-5

1 THE CHAIRMAN: Do we have any
2 final points from the technical experts at this
3 time? -- Members of the audience? -- Panel?

4 MR. MacDONALD: Mr. Chairman,
5 I could say going back to the retaining walls
6 I do have specific sections and unfortunately
7 they are up in my room, and I can give them to Mr.
8 Fox for tomorrow, you know, so we can deal directly
9 with the area you are talking about. I have
10 sketched the two to one slopes on and retaining
11 walls and I do have section site specific that
12 it is possible to look at.

13 THE CHAIRMAN: In order to make
14 this as expeditious as possible, maybe you and
15 Mr. Fox could sometime have a look at what you
16 have got and I can know then whether you are in
17 agreement or disagreement without trying to stretch
18 plans out and discuss the whole thing. It is
19 rather a difficult forum to go into that.

20 MR. FOX: Maybe we can do it,
21 you know, downstairs here -- no problem.

22 THE CHAIRMAN: I think I hear
23 a hint here.

24 MR. MacDONALD: Wait until he
25 finds out I drink water!

26 THE CHAIRMAN: That will maintain
27 your independence. I think at this point unless
28 there is any further questions or points anybody
29 wants to bring up, I will now adjourn the meeting
30

1 until this evening.

2 This evening we have a general
3 session and we have a couple of presentations
4 from groups to take and we also have the question
5 of work camps. So we will now adjourn until
6 7:00 o'clock. Thank you.

7

8

--- Adjournment at 4:50 P.M.

ROGERS PASS ENVIRONMENTAL
ASSESSMENT PANEL

In the matter of Public Meetings of the
Environmental Assessment Panel on CP
Rail's proposed new track development
in Rogers Pass.

PANEL MEMBERS:

P.J. Paradine -- Chairman
Dr. W. Ross
Mr. G. Tench

Held in the Sandman Inn, Petroleum Room,
Calgary, Alberta, on Friday, the 10th day
of June, 1983, at the hour of 7:00 p.m.,
Local Time.

PM-A-1

1 THE CHAIRMAN: (Mr. Phil Paradine):

2 Good evening Ladies and Gentlemen:

3 I am Phil Paradine, Chairman of the Environmental
4 Assessment Panel reviewing C. P. Rail's proposed
5 work in Rogers Pass in Glacier National Park, and
6 the other members of the Panel are on my left:
7 Bill Ross and George Tench. I did make some
8 opening remarks this afternoon explaining the
9 nature of our review. I will not repeat these
10 again these evening. What I would like to do
11 is right away provide the opportunity to any
12 members of the public who want to make a presenta-
13 tion to come forward. M.P.P.A.C. is registered
14 to speak this evening. I am not sure whether
15 they are here yet. Is a representative of
16 M.P.P.A.C. here? -- Evidently not.

17 I guess in that case we would
18 proceed immediately to a presentation by C. P.
19 Rail if your man is here, and I believe C. P. Rail
20 would like to address the question of work camps,
21 and we will get back to M.P.P.A.C. when they
22 turn up.

PM-A-2

(Fox)

MR. JOHN FOX, (C. P. Rail):

If I am missing my bear expert,
he will probably come in while I am carrying on
here.

Ladies and Gentlemen, Mr. Chairman:
Prior to the April, 1982 hearings C. P. Rail
requested permission to construct work camps at Flat
Creek and Beaver. These camps were to be esta-
blished at two previously disturbed sites and
operated from 1984 to 1988 to house construction
crews for the Rogers Pass tunnel and ventilation
shaft.

Concern was expressed that bears
may be attracted to the work camps, which could
result in danger to the occupants and the need
to trap, remove or destroy the bears. There was
also an indication that Flat Creek was an area
traditionally used by caribou. As well, questions
arose about our plans for the water supply and
sewage systems at both camp locations.

To investigate the bear and caribou
concerns, we gathered information on campsite
history and known use of the areas by the two
species. Our findings, detailed in the report
submitted for the hearings, indicate that both
sites were occupied for considerable periods of
time without serious bear incidents. Flat Creek
was operated for several years as a boys' camp
with tents as living accommodation. The conclusion

1 (Fox)

2 reached on bears at both sites was that very
3 intensive management and fencing was recommended
4 to reduce to the minimum^{the} potential for conflict
5 with bears. Our consultants also concluded
6 that there was little chance for negative effects
7 on the small caribou population.

8 Parks Canada were presented with
9 our findings in February, 1983 and supplied with
10 a draft report in March. At a review meeting
11 in April, 1983, Parks Canada informed C. P. Rail
12 that although they found the report satisfactory,
13 they were going to oppose the camps in the park
14 in principle and the reasons given were:

15 Firstly, site disturbance:

16 They felt that the potential exists for disturbance
17 outside camp boundaries during their operation.

18 Secondly, loss of park facilities:

19 Both areas are presently used a trail heads.

20 Thirdly, aesthetics:

21 The camps will be a source of undesirable noise,
22 odour and light.

23 Fourthly, social:

24 Large work camps can lead to unpleasant social
25 experiences for park visitors at picnic areas,
26 campgrounds and other park facilities, and

27 Lastly, environmental:

28 They list wildlife conflict at camps, potential for
29 pollution from sewage and fuel storage, increased
30 bear relocations, and impeded access from

1 (Fox)

2 Trans Canada highway during high traffic volumes
3 as further reasons to oppose the camps.

4 We made our requests for the
5 Flat Creek and Beaver site known to Parks at
6 least two years ago. We are concerned that
7 after all that time we are suddenly presented
8 with these new reasons to deny us the camp sites,
9 especially when it was stated to us when we
10 developed the study guidelines with Parks that
11 their only concerns at the camps were for bear
12 and caribou.

13 One of the major factors against
14 relocating the camps outside the National Park is the
15 increased travel time from outside camp sites.

16 An alternative camp site to the Flat
17 Creek location was found at Illicellewaet Siding
18 located about 5.5 miles west of Flat Creek. An
19 alternative to the Beaver Camp was found 9.6 miles
20 east adjacent to the Trans Canada Highway at the
21 Rogers Pusher Terminal turnoff. The additional
22 travel time for outside the Park camp sites (from
23 the outside sites to the point where the route
24 passes the sites inside the Park) was estimated
25 at 17 minutes for the west portal work force
26 and 22 minutes for the east portal work force.
27 All travel time for construction workers is paid
28 at double time. Given an average cost per man hour
29 to C. P. Rail of some \$40.99, this amounts to an
30

(Fox)

1 average hourly rate for travel of some \$81.98.
2
3 The bare minimum total estimated cost of relocating the
4 camps outside the Park is approximately \$33.3
5 million. Over the entire life of the project, the
6 estimated lost time due to additional costs will
7 also arise due to additional vehicle costs,
8 maintenance, escalation, et cetera.

9 Also, the further the camps are
10 from the worksite, the greater the risk in
11 encountering delays, particularly during the heavy
12 winter snow conditions. Considering these
13 uncertainties, the contract would certainly
14 increase its estimated cost to a total of
15 around \$38 million to account for the additional
16 travel.

17 We have identified alternatives
18 in the Park and have found one that is a suitable
19 alternative to the Flat Creek site near the
20 Glacier Siding. Illustrations of the site are given
21 on the side panels, and the proposed camp locations
22 are as follows:

23 Flat Creek: This camp would
24 house 420 men. A detailed layout of the camp is
25 submitted separately from this Report. The site
26 is an existing flat, disturbed area and will require
27 very little work to improve. There is sufficient water
28 available either from the Illicellaweat River or
29 a well. An adequate area exists for the camp to
30

(Fox)

1
2 be constructed. The Flat Creek site was occupied
3 from the early 1900's to the early 1970's by
4 wardens. In the 1970's, a conservation corps
5 camp was run for boys and in 1979 all buildings
6 were removed.

7 Beaver Camp Site would house
8 460 workers. There is sufficient water available
9 from a well or Connaught Creek. This site was used
10 as a camp by the crews working on the Trans
11 Canada highway between 1951 and 1954. This site is
12 a flat disturbed area and will require very little
13 work to improve.

14 This site at Glacier is located
15 on a plateau above the west portal of the
16 Connaught Tunnel. The site is presented as an
17 alternative to the Flat Creek camp site. The
18 proposed camp would house some 420 men. The site
19 was used for a camp site during highway construction,
20 and I might also say when we were constructing
21 the Connaught Tunnel. Operators for the west
22 portal facilities were apparently housed at this
23 site for a number of years. A detailed layout
24 of the camp has also been produced. This is the
25 site that C. P. Rail prefers in lieu of the Flat
26 Creek site.

27 We feel that the concerns of
28 Parks Canada can be reasonably addressed by
29 establishing the camps in sites previously used
30 for similar facilities. It is proposed to build

(Fox)

1 the camps with landscape and other considerations
2 with emphasis on protection of existing vegetation
3 and visual qualities of the area. We are proposing
4 several strict construction and management procedures
5 which will minimize the effects of the camps on the
6 Parks environment and users.

7
8 Management: C. P. Rail recognizes
9 the need for thorough development and planning
10 of the design, construction and operation of the
11 camps. Recognizing that tunnel contractors may
12 have other immediate priorities, and that planning and
13 design are necessary before award to these contractors,
14 C. P. Rail has decided to handle through a designated
15 contractor the total turn-key development and
16 execution of the camps. This will give C. P. Rail
17 the greatest degree of control and influence over
18 the operations to meet the terms and conditions as
19 laid out and as per agreement.

20 All buildings utilized will be of
21 modular construction, completely assembled and
22 trucked to the site. All buildings will be
23 interconnected by fully enclosed walkways, limiting
24 sound emissions. Construction activity should
25 be limited to 8 to 10 weeks at the project on-set
26 and 4 weeks at the completion. Installation shall
27 be by a crew of approximately 30 men using trucks
28 and cranes. The crews, that is the erection crews,
29 will commute to accommodation. That is, they
30 will stay outside the Park at either Golden or at

(Fox)

1 Revelstoke. We hope to start construction in
2 September of this year, immediately following the
3 Panel's approval. All services will be installed
4 and above ground utilidor, including fire lines,
5 readily savageable at project completion.

6 Layouts of the camp buildings
7 will minimize site disruption and provide
8 separate kitchens and offices from sleeping
9 accommodations.

10 All buildings shall have snow roofs
11 and aesthetically coordinated trim and skirting
12 as shown on the drawings. Units will be double-
13 decked where possible to minimize space requirements
14 within the cleared areas on the sites. The kitchen
15 will be of new construction and specially designed
16 to provide for the following features:

17 Bear proof grocery storage,
18 Bear proof garbage storage, and
19 Efficient ventilation and exhaust to
20 minimize escaping odours.

21
22 The camp will be managed by the
23 turn-key contractor responsible for the design
24 and construction so that all plans and systems
25 are implemented as initially approved.

26 There will be a gate house
27 manned 24 hours per day with a fire patrol and
28 security. A gate on the access road will also
29 restrict traffic.
30

(Fox)

On site-parking or parking in the National Park will be forbidden to all camp residents. Contractors will provide parking areas in the Revelstoke and Golden areas and bus transportation to and from town and to and from work sites. This will minimize "in Park" areas needed and traffic flow congestion. The cooperation of the British Columbia and Yukon Territory and Building Trades Council is required to implement and enforce this rule.

Each camp shall have a resident camp manager at all times on the premises whose responsibilities will include enforcing camp rules and regulations and enforcing operational guidelines, especially those pertaining to the National Parks.

No firearms shall be permitted.

Feeding of animals shall not be allowed. Residents shall be subject to immediate dismissal for feeding animals.

Garbage shall be hauled from the camp daily to an approved dump outside of the National Park. It shall be stored in bear proof steel compactor bins near the kitchen.

Snow shall be removed from campsites to an approved location outside of the camps and to an approved site within the Park.

Strict rules shall be drawn up with Parks Canada's assistance to establish

1 (Fox)

2 guidelines for resident activities outside of the
3 camp boundaries.

4 The sewage treatment system shall
5 be of the rotating biological compactor or an
6 R.B.C. type and capable of meeting Environmental
7 Canada "Guidelines for effluent quality and
8 wastewater treatment". For a camp this size the sewage
9 plants would be enclosed.

10 It is proposed to twin the system,
11 providing an exact duplicate of the rated system with
12 an independent power source. This will ensure
13 that there are no accidental discharges of
14 unprocessed sewage or waste water into the
15 adjoining creeks.

16 An effluent will be monitored
17 by a member of the full-time camp maintenance
18 team to ensure adherence to the proper standards.
19 A complete parts and maintenance package would be
20 kept on site. Sewage plants would be enclosed.

21 Water is available at the sites
22 in wells. If this source is insufficient, water
23 will be drawn from adjoining creeks, pumped to
24 storage tanks within the camps and circulated by a
25 pressure system. Fire water storage will also be
26 provided. Treatment is not anticipated, but
27 clarification may be necessary during spring run-off
28 by means of a simple sand filter system.

29 Power for the camps will be
30 supplied initially by diesel generators housed

(Fox)

1 in vans or buildings. Special attention will be
2 given to muffling noise both from camp residents
3 and the Park environment. It is hoped that by
4 late 1984 to convert camps to hydro-electric
5 power. A full-time maintenance man will be available
6 to service generators in case of a breakdown.

7
8 Propane gas will be supplied for
9 kitchen cooking, fuel and bunkhouse heating.
10 Storage shall be in approved tanks mounted on
11 concrete and protected from vehicular traffic.

12 Camp lighting will be the
13 minimum acceptable. Because of enclosed walkways
14 and restricted parking, very little exterior lighting
15 is needed. This will minimize the lighting effect
16 on the Park environment.

17 Following dismantling and removal
18 of the camp, it is possible within 4 weeks to totally
19 reclaim the site. All materials would be removed
20 along with all services and buildings. Recontouring
21 of the land, replanting or reforestation would be
22 done under the direction of the Parks.

23 Parks Canada will be consulted
24 before removal of services to determine if they
25 would like any of the services left to facilitate
26 campground or picnic area construction.

27 Now to the question of bears. I
28 could almost say it is getting me down but I will
29 not. It has been recommended that we fence the
30 entire perimeter, and I might say that this is our

(Fox)

1 consultant who made this recommendation, that
2 we fence the entire perimeter of both camps to
3 reduce to a minimum the potential for serious
4 conflict with bears. We have considered this
5 recommendation. However, we are faced with a
6 dilemma. The perimeter fence would require
7 considerable clearing at all sites. Parks will
8 not allow this. The fence also presents snow
9 removal difficulties.
10

11 We, therefore, feel that the
12 compromise we are suggesting is the best one from
13 a practical point of view.

30

B-1

1 (Fox)

2 We propose to construct a fence
3 around the garbage compactor, loading dock and storage
4 room access. This fence will be electrified and
5 built so that it can be removed during the bear's
6 dormant period, December through March, which is
7 coincident with the heaviest snow season. This fence,
8 coupled with the fact that strict regulations can be
9 enforced because the camp will be owned and operated
10 by C.P. Rail will, I am sure, give the highest level
11 of protection of any facility in the Park.

12 We feel that the combination of
13 daily removal, strict operating procedures, odour
14 suppression, and high levels of sanitation,
15 combined with Dr. Herrero's preferred design of
16 electrified fence in this area, maximum effects can
17 be achieved for ten percent of the cost of full
18 fencing with no additional forest cover removal.

19 The Environmental Coordinator will
20 have, as one of his major duties, the job of ensuring
21 the camp bear management standards are strictly
22 adhered to.

23 I have asked Dr. Steven Herrero,
24 who has worked with us over the past year, to discuss
25 his thoughts on the bear management aspects of the
26 camps.

27 At this time I would like to ask
28 Dr. Herrero if he would come up and say a few words,
29 please.
30

B-2

1 (Herrero)

2 DR. STEVEN HERRERO: Thank you, Mr.
3 Fox. I think for those of you who are interested
4 in the details of what can be done to separate bears
5 and people, the report which I submitted is a better
6 source than the oral comments which I will make
7 because I was able to clearly organize things there.

8 Essentially, I started out -- you know,
9 you can lay things out one by one and step by step
10 in the report. I started out with the knowledge that
11 black bears could be kept out of bee yards and
12 camping areas by virtue of electric fencing. I was
13 skeptical that the state-of-the-art technology
14 was sufficient or sufficiently demonstrated to be
15 able to recommend that grizzly bears could. However,
16 I canvassed all of my colleagues in North America
17 who are working in this area and they convinced me,
18 by virtue of looking at multiple sites where
19 electric fencing had been used, very high standard
20 electric fencing, where electric fencing had been
21 used to keep grizzly bears out of work camps and
22 out of the dump in Jasper Park.

23 In fact, in Jasper Park the
24 electric fence was put up after the bears had
25 habitually used the sanitary landfill, as it is
26 called, for several years, and it was successful in
27 keeping them out. So I reached the conclusion that
28 the state-of-the-art technology was such that a
29 fence built to high standards would serve as both
30

B-3

1 (Herrero)

2 an electrical and a physical barrier to bears, and
3 those standards are specified in the report which
4 I submitted.

5 It was not my purpose in generating
6 this report to comment on the desirability of
7 locating the camps inside or outside of the Park and
8 I do not comment on that, and I will not here,
9 particularly.

10 However, I did report that there
11 was a feasible technology, or what appeared to be
12 a feasible technology to keep bears out of camps.
13 Now, that technology, it turns out, is fairly
14 expensive and Mr. Fox suggested that it would cost
15 something like \$100 to \$150 per foot to construct
16 the fence which I recommended, and the total cost
17 would be somewhere between \$125 and \$250,000 for
18 each camp. So, I will let that be thrown into the
19 economic hopper because I know there are a number of
20 larger figures being bantered about related to the
21 location of the camps.

22 There was, however, several
23 unresolved issues regarding the camps and their
24 function with regard to bears which I brought up
25 in the report and are worth mentioning here.

26 Probably the most important one
27 is an engineering problem which I never fully resolved
28 in my mind, and since then, I have not seen fully
29 resolved by any of the proposals. However, there
30

B-4

1 (Herrero)

2 has been quite a bit of work done on it, and that
3 is the question of whether this fence, which is
4 essentially a cyclone fence, if it were to be
5 built, inside or outside of the Park, this cyclone
6 fence eight feet tall, electrified system, whether
7 it could be maintained with the high snow loads that
8 occur in Glacier Park. Somehow or other, that snow
9 has to be removed or it is very likely that the
10 combined snow movement or snow creep would probably
11 do serious damage to even the stoutest fence.

12 Now, one of the things I suggested
13 in the report was the possibility of metal sleeves
14 in the ground whereby the fence could be removed
15 from December 1st through about April 1st. Now,
16 there would be a few bears out during the time when
17 the fence would be removed, but another thing that
18 I recommended in the report was that the garbage
19 facility and kitchen area be built to bear-proof
20 standards in addition to the electrified fence on
21 the outside. In other words, I recommended multiple
22 levels of protection against bears so that if one
23 system failed or one system had to be taken down,
24 then there would be a backup system.

25 But the snow problem and the snow
26 removal problem has never been completely detailed
27 to my satisfaction and remains something which is
28 a crucial factor. It is identified throughout the
29 report. I know C.P.R. has been concerned about it
30

B-5

1 (Herrero)

2 and has done quite a bit of design work, but it is
3 a factor which could result in the fencing being
4 ineffective.

5 A second very important factor
6 in the maintenance of camps in bear areas I got from
7 talking to some of my colleagues in Alaska who had
8 experience in designing the Trans-Alaska pipeline
9 system of camps. One fellow in particular was
10 responsible for bears and other carnivores and their
11 interaction with those camps. TAPS was a big
12 project which went through very important bear
13 country, both black and grizzly bears, however, it
14 was not in high snow fall areas. There was really no
15 precedent with regard to the snow load problem which
16 Glacier would face.

17 But with regard to a lot of men
18 and camps with a lot of food and bear problems, they
19 had them all. It was out of that milieu that these
20 bear-proof or relatively bear -- highly bear
21 repellent -- better than bear-proof. They always
22 find a way to baffle somewhat the best design. These
23 are good. They will go several years without
24 penetration.

25
26 At any rate some of the other
27 problems that they encountered there are worth
28 mentioning. These were related to the workers
29 themselves in trying to maintain a degree of control
30 over what the workers did in their off hours. One of

B-6

1 (Herrero)

2 the most persistent problems that occurred was
3 workers who would bait bears or go out in some way
4 looking for pictures or thrills or to commit suicide
5 or what, I have no idea, but there were persistent
6 problems which were caused by virtue of workers' off
7 hour activity attracting bears for one reason or
8 another or interacting with bears for one reason or
9 another. On TAPS they found that it was not
10 sufficient to simply fire the workers, which they
11 did. It was policy that any worker doing that would
12 have to be fired. It was not sufficient because
13 they could move to another camp somewhere far enough
14 away that I guess the record transfer was not
15 complete enough, and the worker would be hired back.
16 Eventually they implemented a policy whereby not
17 only the worker would be fired, but the foreman would
18 be fired as well if one of his workers was convicted
19 of baiting bears.

20
21 Now, I do not know how they ever got
22 that through the union, but that is probably the
23 most marvelous thing about the whole affair.

24 At any rate, the workers themselves,
25 in their activities not related to construction,
26 are a problem which requires a serious degree of
27 management, and that has to be worked out with
28 union regulations and has to be made feasible and
29 humane and everything else and I identify the problem
30 and suggest some of the solutions which worked in

B-7

1 (Herrero)

2 Alaska. But it is something that is worth
3 mentioning and worth underlining.

4 Finally, I think I would like to
5 mention the sort of overall integrated system that
6 I saw if the camps were to be constructed in the Park.
7 Ideally I would like to see it implemented if the
8 camps were constructed outside of the Park, but the
9 realities are such that much tighter environmental
10 management regulations, it is my understanding, will
11 be implemented if the camps are in the Park versus if
12 they are outside of the Park because the Province of
13 B.C. is not nearly as strict in its requirements for
14 environmental management or at least with regard to
15 bears as is Parks Canada.

16 The final problem that I want to
17 identify and just briefly comment on is there is
18 sort of overall management and implementation of the
19 whole system. There is an environmental manager who
20 is sitting over there, Mike McKnight, attached to
21 the project who would certainly have primary
22 responsibility seeing that the fence was turned on
23 at the right moment, that the gates were not left
24 open, that the garbage was not blowing outside of the
25 fence, that workers were not baiting bears and all
26 these myriad of other factors.

27 But I did propose in my report
28 that a team of people who had experience in managing
29 camps and managing problems in bear country also
30

B-8

1 (Herrero)

2 be established to assist Mr. McKnight in the
3 inspection and to sort of identify problems at
4 least as they start if not before they start. You
5 know, once the camp was designed or in the process
6 of the camp design to take a look at the management
7 of the kitchen and to take a look at the management
8 of the fence, because it is one thing to build a
9 fence; it is another thing to properly manage it.
10 It is one thing to have workers there, another thing
11 to have some degree of control over off hour
12 activities. These camp locations are indeed in
13 good quality bear habitat with a lot of bears
14 around, so the potential for problems is a very real
15 one.

16
17 I am at the same time sensitive to
18 the comments which I think I just came in on the tail
19 end which Mr. Fox has made, that perhaps C.P.R. is
20 being forced to perform to much higher standards than
21 other operations have, and I think the experience of
22 the Northlander and Parks Canada themselves, to the
23 extent that they are in analogous situations is
24 somewhat of a guideline.

25 I do think it is possible with
26 a full perimeter fence to maintain a bear-proof camp,
27 but it would require a lot of focus and follow-
28 through.

29 Now, what would happen if these
30 camps were just put there without any fence whatsoever,

B-9

1 (Herrero)

2 or with a partial fence is I think a very likely
3 series of bear-related problems. How serious they
4 would be would depend on how serious the opportunities
5 were for bears to prowl through camp or to be
6 attracted by odours which led them to something to
7 eat. Odours by themselves do not do much, they are
8 merely an attractant. If there is not something to
9 eat that follows, then the bears quickly learn to
10 go away. So complete sanitation or complete isolation
11 of bears and garbage is important.

12 But I was concerned, and I indicated
13 this to the C.P.R. that the partial fencing solutions,
14 largely because the camps are built right against
15 the edge of the forest, which from the environmental
16 point of view is probably a good choice because it
17 makes maximum utilization of the site, but the bears
18 also make maximum utilization of the forest so that
19 they have an ideal situation to approach from. They
20 will use the forest right to the edge of the camp
21 as cover, both species, and will approach much more
22 readily than if the camps were in the middle of a
23 huge open area. This is especially true of black
24 bears which are more reluctant to leave the forest than
25 are grizzly bears.

26 So the partial fencing solutions,
27 while they might do a really good job of isolating
28 garbage from bears, they might not, too, if workers,
29 I do not know, go into town and buy snacks and throw
30

B=10

1 (Herrero)

2 things out the window or sit around outside eating
3 and throw things: I do not know how that would work.
4 But at any rate, there might be bears exploring
5 through camp just because of the fact that the
6 cover comes up to the edge of the camp. At any rate,
7 the potential danger that is there would be probabilis-
8 tically very slight, and I suppose could be traded
9 off against the cost of full perimeter fencing versus
10 partial fencing.

11 I think what I would say by way
12 of summary of my thoughts on camps potentially being
13 located in the Park, in summary, I think there is
14 potentially a feasible technology to keep bears out
15 of these camps and it would require all of the
16 enabling mechanisms to make it work, and it would
17 require answering the questions of snow removal, which
18 would be essential for the function of the fence.
19 At the same time, I do not comment and have not
20 commented from a Parks point of view whether it
21 would be desirable or from C.P.R. point of view whether
22 it would be desirable to have the camps inside or
23 outside of the park.

24 MR. FOX: Thank you, Mr. Herrero.

25 I would also like to ask Mr. Jack O'Neill to say
26 a few words to the Panel on camp operation. Mr.
27 O'Neill is Chairman of National Caterers Limited,
28 a Vancouver firm and he has been operating camps
29 I might say all through British Columbia and

northern Alberta for the past 23 years, and I am
sure perhaps he can enlighten us on what camps are
and how they can be operated and what you have to do.
Mr. O'Neill.

B-12

1 (O'Neill)

2 MR. JACK O'NEILL (National
3 Caterers Limited): Thank you, Mr. Fox.

4 Mr. Chairman, Board, ladies and
5 gentlemen, National Caterers is not just a catering
6 company. It is what we call a turnkey company.
7 We have three or four different arms within the
8 company, and since 1962 we have been installing the
9 complete camp with our own trailer fleet, our own
10 construction arm and naturally do the feeding after
11 this camp is installed.

12
13 In the case of many of our
14 installations, we start right off the bat working
15 with the environmental people, working with the
16 water resources, planning the site and the source
17 of the water which is quite important, and then we
18 go about clearing the site, bringing the equipment
19 in to lay out the utilidor, the light plants,
20 bringing in the trailers and then, as I say,
21 eventually feeding.

22 At the end of the project, through
23 agreement with whichever regulatory body it is and
24 however they would like it, we have even turned
25 camps into air strips, replanted them and as you can
26 see, those are some of the camps that we have
27 installed since 1962 in Alberta and B.C. We do have
28 the pleasure of installing and feeding about 95
29 percent of the pipeline projects in Canada. I guess
30 we did about 80 percent of the transmission line. We

B-13

1 (O'Neill)

2 did 100 percent of the B.C. Railway construction
3 and all their camps and we are presently doing a
4 number of large installations and running them,
5 managing them and managing the environmental, every-
6 where from Quintet where we have sort of a
7 maintenance and we do every bit of maintenance on
8 the Quintet crow project from the buses to running
9 the sewage treatment plants to installing you name
10 it, and even the warehousing, doing the truck repair.
11 So we cover all phases, not just feeding, and we
12 have been doing that, as I say, since 1962.

13 The subject of bear and bear
14 control I know is a bit of a touchy item. We have
15 had and have been located in I suppose any place
16 that there are bears, from national parks to swan
17 hills to far north to the B.C.R. where we had any
18 number of bears, and the complete, in my mind, secret
19 or answer to bear control is the control of your
20 garbage and removing that garbage far enough away
21 from the camp so that there will be no attraction.

22 Compounded with the problem of
23 the garbage dump are the odours around a kitchen that
24 you eliminate. In looking at the problem in the
25 parks, we would propose bear-proofing, which is
26 metal lining under the floor of the storage and
27 garbage area and electrifying the perimeter on the
28 loading zones and in the garbage storage area.
29 What it would be is a garbage compactor. Now, these
30

B-14

1 (O'Neill)

2 are proven and as a matter of fact, I see one
3 about every three weeks at Whisler. They had bear
4 problems in two of their dumps. They tried everything.
5 They finally have settled on an electrically controlled,
6 you open up heavy plate doors and you dump in your
7 garbage. Immediately that activates the motor which
8 moves the garbage along, compacts it and puts it
9 into another area. Then we would be unloading
10 that probably twice a day, but bears just cannot --
11 it is thick plate steel; they just cannot get
12 anywhere near it. So even if they came up to it,
13 they do not have a lunch and you keep it well
14 disinfected with Pinesol and mothballs and things.
15 That just throws them right off the scent.

16
17 We truthfully have had very -- it
18 goes back many years that we have had any bear
19 problems even around the back of the kitchen. The
20 back of the kitchen is where the bears go. In the
21 operation of a camp, cleanliness is number one; the
22 grounds, the bunkhouses, the rec hall and the
23 kitchen, and the removal of the garbage from the
24 site on, you might say, a twice daily or at least
25 a daily situation.

26 We would certainly plan on working
27 with the Parks people and having them direct us
28 to where they would like us to dump both the garbage
29 and the snow, and certainly we would form committees
30 not only on fire patrol, as we usually do, but

B-15

1 (O'Neill)

2 certainly on inspection and the control and
3 implementation of the rules controlling, as was
4 discussed, feeding of bears, petting of bears or
5 having them as pets as I have heard happen. So it
6 is really an overall controlled camp, controlled
7 garbage situation, controlled egress and ingress
8 of food stuffs. I think that problem -- a bear fence
9 I have not viewed, but I think this is a doubly --
10 it will solve the problem twice over with the
11 container by itself, then surrounding your whole
12 food area, service area with an electrified fence.

13 MR. FOX: Thank you very much,
14 Mr. O'Neill. Mr. Chairman, we have looked, as you
15 can see, very thoroughly into this matter and we have
16 not reached our conclusion very lightly.

17 One of the problems that we really
18 have, and I certainly respect Dr. Herrero's advice,
19 and he alluded to the problems of snow, and this
20 is a very serious problem. With the amount of snow
21 that we get in the Glacier National Park area, I am
22 sure heat trace in setting concrete would not nearly
23 be sufficient to melt the snow that we get in that
24 area. I think all we would end up with is an
25 iced up tunnel with the snow above it, and the only
26 sure way, if we are going to keep the fence the year
27 round around the camp, the only sure way to remove
28 snow is to do it mechanically.

29 That would require sufficient room
30

1 outside of the fence to operate such things as
2 frontend loaders or a snowblower and have a place
3 to place the snow. This, of course, would require,
4 in the sites that we are looking at, removal of
5 a 30 foot fringe of trees.

6
7 Now, that is our dilemma. If we
8 are allowed to go into the Parks with our camps and
9 we are forced to put up bear-proof fences which I
10 would do rather than have people subjected to
11 bear attacks or anything like that, but I would
12 have to have sufficient room beyond the fence to be
13 able to fully maintain that fence year round.

14 So, the alternative to that is,
15 as Mr. O'Neill has described and I described it myself,
16 and I fully realize that fencing your garbage and
17 your food areas does not protect the man from the
18 bear, as Dr. Herrero has suggested and recommended.

19 However, whichever way we go,
20 I still want the camps in the Park for the reasons
21 that I have outlined, and I see no reason why any
22 company should be put to an expense of the order of
23 \$30 to \$40 million due to additional travel time
24 over a four year period because somebody figures
25 that the camp might be a nuisance. Now, I have got
26 to have a better reason than that to go to my
27 management and the people of this country and say,
28 hey, you are going to have to anti up another
29 \$40 million in freight charges because. I will leave
30 that with you.

1 Having said all that, that is
2 our camp presentation and we are certainly open to
3 any questions and any suggestions too.

4 THE CHAIRMAN: I think we will
5 be getting to you with questions, but I think this
6 quite naturally leads into Parks Canada, and I do not
7 know whether you prepared a presentation, but I think
8 at the minimum I think we would be hearing from you
9 your reasons for not wishing to have the camps in
10 the Park, if I understand that to be your position.

1 (Leeson)

2 DR. BRUCE LEESON (Parks Canada):

3 We made our first indication to C.P. Rail that we
4 did not want the camps in the Park in April. That
5 was following nearly a year of discussions and
6 research and investigations about camps being in the
7 Parks, which began at your hearings a year ago now.

8 At that time, we were equivocal
9 about it and we were somewhat surprised to hear so
10 many people comment at the hearings and to us
11 afterwards that they thought camps in the Park were
12 a bad idea. So we determined that we had better be
13 more cautious about the whole concept, and suggested
14 to C.P. Rail that they should investigate the issue
15 very thoroughly because there were a lot of
16 points to be attended to.

17 They did so and have reported
18 tonight about their research, and we think the
19 research has been well done with regards to the
20 wildlife, at least, that is reported in this document.
21 It is determined that there is probably not a caribou
22 problem and we agree with that. It is determined
23 that there would be a bear problem and we agree with
24 that.

25 Now, Dr. Herrero has done a
26 commendable job, we think, of investigating what the
27 nature of the problem might be in terms of
28 similarity with other camps in the Interior mountains
29 of British Columbia.
30

1 (Leeson)

2 When we read the solution, it
3 was quite alarming, of course. The treatment proposed
4 to keep bears away that Dr. Herrero describes in
5 his report we think would be very effective, probably
6 the most effective we have ever seen. I suspect you
7 have read and others may have too that it requires
8 substantial impact on the Park, in addition to the
9 fence, which would have to be protected by snow and
10 requires the 30 foot strip around the outside and
11 inside too, I suppose.

12 It is also proposed that a 300 metre,
13 that is approximately 1,000 feet cleared zone outside
14 of the fence would also be required. Well, that
15 greatly enlarges the impact on the Park that the
16 camp would constitute. That is very alarming for us
17 because the sites were probably very minimal to
18 start with. It would require a really cramped camp,
19 and at that time we were talking about two camps for
20 250 men each.

21 So with that information at hand
22 and other things that we had seen at other camps and
23 other information that we had received about camps,
24 we concluded that we could not endorse the camps
25 in minutes of our April meeting with C.P. Rail and
26 we stated the following, that substantiated our
27 request that they withdraw their proposal to put the
28 camps in the Park.

29 First we said that the camps would
30

1 (Leeson)

2 not contribute to the short term preservation,
3 understanding or interpretation of Glacier National
4 Park. Any object, any activity that is proposed
5 on national parkland has to be judged against those
6 criteria because that is our business, that is what
7 we do; we provide understanding of what is being
8 preserved and we provide interpretation, and the
9 camps contribute to none of that. As a matter of
10 fact, they detract from all of that.

11 Secondly, we said that the camps
12 would cause short term destruction to visitor
13 activities and create environmental impact. We
14 thought that the disturbed areas being proposed for
15 the camps were insufficient and substantial expansion
16 would be implied.

17 Thirdly, the camps provided no
18 short term or redeeming residual merits to promote
19 their presence in Glacier National Park. There was
20 nothing that the camps could give to Glacier Park,
21 either for the visitors or for the operation, either
22 in the short term or in the long term.

23 So with that information provided to
24 C.P. Rail, we said that when the hearings were coming
25 up we intended to oppose the camps and we so
26 advised you in our first communication with you.

27 We are doing this on this basis,
28 that this Panel and this group has been called for
29 people and for you to identify opportunities to
30

1 avoid impact on Glacier National Park as a result
2 of this project which is deemed necessary and for
3 people to suggest alternatives. We have alternatives
4 to suggest. Where we did not look through railway,
5 there was no alternative; it could not go anywhere
6 else. There is an alternative for the camps and
7 to the west, a large cleared area adjacent to the
8 Trans Canada Highway and to the railway tracks and
9 water exists approximately six minutes driving west
10 of Flat Creek, nine kilometers west of Flat Creek.

11 It is a site about ten times as
12 large as Flat Creek. It has been subjected to
13 industrial activity and would be available, we think,
14 as an alternate to Flat Creek. For the east camp,
15 that is the Beaver River Valley camp, east of the
16 Park there are many clear cut areas available. All
17 have access to them. The best ones have water available
18 and they have very large areas where the bear
19 defences that have been proposed could be implemented
20 without any clearing and also the west site could
21 too.
22
23
24
25
26
27
28
29
30

PM-C-1

(Leeson)

1 So on that basis we are here
2 to say that we think the camps represent an
3 intrusion in the Park. They are contrary to
4 National Parks policy. They are contrary to
5 National Park plan for Glacier Park. There is
6 an alternative. We have identified what the
7 alternative is and we are suggesting that this
8 Panel consider that and we are asking, in conclusion,
9 therefore, that the camps not be permitted in the
10 Park.
11

12 THE CHAIRMAN: Okay, I think that
13 is clear enough as a position statement. Thank you.

14 I have a question to start off
15 the questioning and this is the control of the
16 workers. Somebody mentioned, I believe, it was
17 Steve Herrero, the Draconian measures that we
18 used in the TAPS projects in order to deal with
19 conflicts. I would like to pose a hypothetical
20 situation. If a camp was in the Park and there
21 were problems, how could Parks deal with these
22 problems? If you had somebody causing problems
23 facing a bear or something lesser than that, what
24 measures would you have for dealing with that
25 individual if the camp was in the Park? What
26 could you do? Could you ask him to leave the Park
27 entirely or would you have to go and see C.P.
28 and say this individual was just causing a problem.

29 DR. LEESON: That is completely
30 to ourselves. Our only option is to use the

PM-C-2

1 National Parks Act to charge somebody who is
2 actually interfering with wildlife -- they are
3 feeding it or harrassing it in some way. Now
4 I would expect that there would be an agreement
5 with C. P. Rail and they have stated their
6 preparedness to deal severely with an employee who
7 would be harrassing wildlife, whether they were
8 in the camp outside or in the Park.

9
10 THE CHAIRMAN: Does C. P. have
11 any comment on that question?

12 MR. FOX: I would think along
13 the same lines as Doctor Leeson has suggested, but
14 I would suggest that one thing would have to be
15 done and that was you would have to very definitely
16 ensure that you could identify the individual,
17 and I would suggest that under the powers of the
18 Act that govern the National Parks, the first
19 step you should do is place that guy under
20 arrest, if that is what you can do, and then
21 you have got him, and then march him in and take all
22 the necessary particulars, and then we could
23 deal with him on a proper basis. But if you
24 think somebody has done it and you have not got
25 his name, you have not got a case. You have to
26 have a good case before you can get it through
27 the unions.

28 THE CHAIRMAN: It seems to come
29 down to the question that Parks may be losing some
30 control by having work camps in the area, whereas

PM-C-3

1 presumably with campers if you were having problems,
2 you can ask them to leave fairly easily.

3 DR. LEESON: If the infraction
4 was not a really serious one, for example:
5 somebody was picnicking and there was a sign that
6 bears were in the area and they left their picnic
7 site unattended and covered with food, they would
8 likely simply be verbally reprimanded and directed
9 to clean up. In recent years, people have
10 actually been apprehended throwing bran muffins
11 and things -- I mention that because it is one
12 I think of to bears, and they were charged and
13 taken to court and last year the fines were in the
14 order of \$300 to \$500. I can only remember
15 one instance where somebody was actually arrested
16 for being involved with a bear and that was about
17 four years ago on the Icefield Park where a bear
18 approached a man's picnic site and he whipped out
19 his 44 magnum and killed the bear right on the spot.
20 So he was arrested.

21 THE CHAIRMAN: Panel do you have
22 any questions?

23 MR. TENCH: Doctor Leeson, these
24 two camp locations outside the Park would put
25 400 people within easy range of the Park from either
26 end, and I would suggest that the social impact
27 of this would be possibly as great as having them
28 inside the Park with regard to abuse of Park
29 facilities, and maybe more so, because if these
30

PM-C-4

1 campsites were outside, the cars probably would
2 also be parked there, which would make that
3 whole workforce probably far more violent with
4 regard to use or access to the Park facilities.
5 Have you given this any thought?

6 DOCTOR LEESON: Yes, we have,
7 and I do not disagree with you, Mr. Tench, that
8 simply having the camp two kilometers outside
9 the boundary is going to do very much to alleviate
10 the social concerns that exist. We are not
11 imagining that there are substantial social benefits
12 by being outside of the Park, except on the east
13 end probably there would be because then there
14 would be likely a fairly strong attraction to
15 go to Golden for recreation, and so the east-end
16 workers may not use Park facilities too much, but
17 on the west-end, it likely would not make very
18 much difference.

19 MR. TENCH: The putting of the
20 camp in the Beaver Pit would not likely damage
21 the physical facilities of the Park at all, I
22 think. At least, that would be my feeling.

23 DOCTOR LEESON: Did you get to
24 the Pit to see it the other day?

25 MR. TENCH: Yes.

26 DOCTOR LEESON: Probably it is
27 insufficient in size for a camp -- I think that
28 is the 460-man camp, and last Thursday we learned
29 that the camps were not 250 men camps. They were
30

1 420 and 460 men. So they are substantially larger
2 than we had known about before.

3 If we go with the Cadillac bear
4 system, protection system, then we have a 1000-foot
5 cleared area outside the fence, which clearly is
6 very large compared to the size of the areas
7 available.

8 Is anything less than that acceptable?
9 Well, we do not know. Perhaps Doctor Herrero
10 could comment on that, the degree to which the
11 bear protection could be cut down and not jeopardized
12 its continued capability to defend against bears.
13 We were also, I must hasten to add, skeptical --
14 I think that is the proper word to use, about a
15 no-parking. We visited the camp at Revelstoke
16 Dam and the parking is approximately as large as
17 all of the rest of the camp. The camp manager
18 told us that almost every man in the camp had
19 a car there and that was important to them --
20 single men, married men; it did not matter who
21 they were. They usually did not stay more than
22 three or four days in camp before they left for
23 some reason or another, and they use their cars,
24 and we wonder whether a situation might come to
25 pass where we would plan not to have cars; camps
26 would be installed accordingly and nobody would
27 come to work. The trade unions, which you must
28 know are extremely strong in British Columbia, may
29 not agree. Then what would we do?

THE CHAIRMAN: I do believe that in your presentation you mentioned that something would require the cooperation of the unions.

MR. FOX: Right, you certainly have to get the union agreement to the no-parking set-up within the Park and a common pick-up either in Revelstoke or Golden or both.

THE CHAIRMAN: Have you talked to the unions at all?

MR. FOX: No, I have not, not yet.

MR. TENCH: Do you think it is feasible to keep these 400 men in one camp location and really not let them out? Am I seeing the right scene there that they come in four or five days or whatever the length of the shifting is before they are allowed out?

It strikes me as a sort of a prison sentence while they are there.

MR. FOX: That is not the intent at all, Doctor Tench. I think if you look at my remarks and the general comments that I have made for the last two nights, you see I suggested that there would be trips into town during the course of the week -- that would have to be provided.

DOCTOR HERRERO: I would like to clarify what I did say in the report with regard to the desirability of clearing the perimeter around the fence. The recommendation was based on some known behavioural characteristics of black

1
2 bears that they are reluctant to cross open
3 areas. They will cross them especially under
4 cover of dark. They are reluctant to, and the
5 ideal situation if you want to locate a camp,
6 especially in black bear area -- it helps also
7 in grizzly bear area, is to have a cleared perimeter
8 around the outside of the camp and it sets up a
9 situation where bears are more reluctant to
10 approach.

11 I suggested that the ideal with
12 that in mind might be 300 meters. I went on to
13 say that 200 meters would do it and even 100
14 meters would probably get substantial benefit.

15 The design that is being proposed
16 if the full perimeter fence were implemented
17 would pretty well have the fence up against the
18 forest. Now if the fence is properly maintained
19 and the snow loading problems are handled, and
20 the fence is built to the highest specifications,
21 there should still be no problem with bears.

22 It is just -- the reason I recommended
23 the cleared perimeter was just another aspect of
24 this sort of back-up system, just to make it
25 more difficult for bears to approach, but it would
26 not affect the overall function of the fence in
27 any way. If the fence is doing its job, as my
28 colleagues have convinced me it should, then the
29 fact that the fence is right up against the forest
30 should not matter provided that the snow be cleared.

1
2 Now Mr. Fox has thrown out the
3 more realistic figure perhaps of 30 feet needed
4 in order to clear the snow, and again, I am not
5 an expert in snow removal, but I do know that
6 it could be the most serious problem that this
7 fence would face. The 300 meters, with due
8 respect Bruce, was recommended as another one
9 of those sort of ideals and back-up systems, but
10 it is not an essential component of the design,
11 but, however, if the cars were located in a large
12 clear-cut outside of the Park, then there would
13 be less cover for bears to approach.

14 THE CHAIRMAN: I would like in
15 a second to provide an opportunity to the M.P.P.A.C.
16 representative to make a presentation and maybe
17 we can come back to the wildlife issue.

18 The one question that I would
19 have at this time before we go into that is that
20 it seems to me to some extent the feasibility
21 of work camps is dependent on the attitude of
22 somebody that is not here and that is the union
23 in terms of parking, and accepting the fact that
24 people would not be allowed to have automobiles.
25 How difficult would it be for you to get some
26 sort of understanding with the union and inform
27 the Panel of what understanding you have with
28 them?

29 MR. FOX: Well, let me ask this
30 question so I can go to them on an honest basis.

The first part of the paper discusses the importance of maintaining accurate records of all transactions. It is essential for the business to have a clear and concise record of all income and expenses. This will allow the business to track its financial performance over time and identify areas for improvement. The second part of the paper discusses the importance of maintaining accurate records of all assets and liabilities. This will allow the business to track its net worth over time and identify areas for improvement. The third part of the paper discusses the importance of maintaining accurate records of all debts and obligations. This will allow the business to track its financial obligations over time and identify areas for improvement. The fourth part of the paper discusses the importance of maintaining accurate records of all taxes and other legal obligations. This will allow the business to track its financial obligations over time and identify areas for improvement. The fifth part of the paper discusses the importance of maintaining accurate records of all other financial information. This will allow the business to track its financial performance over time and identify areas for improvement.

Can I have parking? If the camps are in the park, can I have sufficient room to park the cars or can I not? That is the issue. If you tell me I cannot, then I have something to go to the union with. Right now I base all my assumptions on the fact that we have limited room, and limited room eliminates parking -- no room for cars.

Now is there any other place in these areas in the Park assuming -- say if we got the camps in the Park, can we have the workers' cars in the Park? Is there room some place for them? You know I have scratched my head and gone and visited sites and I am at a loss to do any more thinking on this thing.

THE CHAIRMAN: I suppose ultimately you could also put them outside the Park with a schuttle service if it came to that?

MR. FOX: Well, you go to the union on that too.

THE CHAIRMAN: Well, I thought the message was fairly clear from Parks in terms of we do not want the camps, so I assume they do not want the cars.

MR. FOX: The answer then, as I understand it, under no circumstances will there be any parking in the Park if we had the camps in there. Is that a correct assumption on my part?

DOCTOR LEESON: That is right - we do not want the camps and we do not want the cars.

1
2 MR. FOX: So even if we had
3 the camps, you would not want the cars because
4 there is no room for them. Would that be a
5 correct statement?

6 DOCTOR LEESON: That is correct.

7 MR. FOX: That would be a correct
8 statement. Okay, so all I have to do then is
9 go to the union and I tell them that Parks Canada
10 will not permit any parking of private vehicles
11 within the Park boundary, therefore, we will
12 propose this and they will not have a leg to stand
13 on. Now there is all kinds of camps where that
14 particular rule is invoked and if you would like
15 to hear some Mr. O'Neill will tell you some.

16 THE CHAIRMAN: That explains it
17 fair enough. You feel that if that position was
18 taken that would be an absolute --

19 MR. FOX: It is outside of my
20 hands. You know, I am completely cut off and I
21 cannot do a thing about it. I have just been
22 told there is no parking. I have to respect that,
23 regardless of what the union might want.

24 THE CHAIRMAN: Okay, fair enough.
25 If we could have the representative from M.P.P.A.C.
26 perhaps come up to make the presentation, and I
27 understand that you have a time constraint, so now
28 might be a good time to come forward and make
29 your presentation.
30

(Cockerton)

1 MR. DON COCKERTON, National &
2 Provincial Parks Association of Canada:

3 Thank you, Mr. Chairman. Ladies
4 and Gentlemen: My name is Don Cockerton. I am
5 speaking here for Kevin McNamee who is the
6 National Program Director in Ottawa for the
7 National & Provincial Parks Association, and I
8 think if there are substantive comments or
9 questions, I shall do my best to answer them,
10 but some may have to be referred to him for a
11 response.

12 Glacier National Park and Rogers
13 Pass are spectacular monuments that attest to
14 the awesome power and beauty of nature. The
15 environmental effects of C.P. Rail's project to
16 twin the existing railway track through Rogers
17 Pass, however, will demonstrate the fragility of
18 this mountain environment for years to come. The
19 range of concerns, the amount of information and
20 the number of documents before us is a testament to the
21 enormous scale and widespread implications of this
22 project.

23 The National and Provincial Parks
24 Association represents the views of some 2,000
25 Canadians. We firmly believe that Glacier National
26 Park should remain primarily representative of our
27 natural heritage, not of man's attempt to dominate
28 nature. Our primary concern is that this project
29 should not compromise the integrity of a national
30

1 (Cockerton)

2 park that will celebrate its centennial in only
3 a few short years. Our Association welcomes
4 the opportunity to appear before this Panel and
5 offer our views on C. P. Rail's project.

6 The Association acknowledges and
7 is pleased with the work of this Panel and of the
8 various steering, environmental and design
9 committees in trying to develop and implement
10 strong mitigative measures. This work is absolutely
11 essential if the impacts of this project are to
12 be less severe than anticipated. It is apparent
13 that from the time the Canadian Transport
14 Commission approved C. P. Rail's application,
15 progress has been made in addressing the environ-
16 mental implications of this massive undertaking.
17 C. P. Rail is to be commended for the way in
18 which it has seriously addressed the concerns of
19 the Panel, Parks Canada, and citizens groups such
20 as ours. It is our understanding that design
21 changes, such as the location of the ventilation
22 shaft, have been invoked to meet stated concerns.
23 We are pleased and hope that this is a reflection
24 of an ongoing commitment by C. P. Rail to use
25 sound environmental engineering practices in the
26 alteration of Rogers Pass.

27 The Association has a number of
28 comments and concerns which we hope will be
29 constructive and serve to remind those involved
30 that we are discussing the permanent alteration of an

(Cockerton)

1 part of our national heritage - Glacier National
2 Park.

3
4 The first area of concern is
5 Terrain Impact. A major concern of the
6 Association relates to the extent and number of
7 large scars and subsequent erosion of these scars
8 as a result of this project. It is the expressed
9 feeling of Parks Canada that slope stability
10 may be more problematic than anticipated. While
11 C. P. Rail's report of June 1983 describes its
12 reclamation program in some detail, measures to
13 prevent slope failures and erosion have not been
14 discussed at length. There has already been
15 one landslide as a direct result of construction.
16 Furthermore, Mr. David G. Walker, in his letter to
17 the Panel of May 16th stated that there was "an
18 unacceptable level of surface erosion", erosion
19 control could be improved at major stream crossings,
20 and that there were slope stability problems west of
21 Stoney Creek. Can C. P. Rail provide us with
22 assurances that proper and effective action will be
23 taken to prevent or mitigate such slope failures
24 that have already occurred?

25 The second area of concern is the
26 Construction Schedule. It is our understanding
27 that the \$600 million plus cost of this formidable
28 undertaking is to be financed by the proposed increase
29 to the Crow Rate. As all are aware, political
30 action on this issue has been slow and no solution

(Cockerton)

1 appears to be forthcoming. Our concern is that
2 if a change in the Crow Rate is delayed for a
3 long period, the pre-construction work will sit
4 and fuether slope failures may occur resulting
5 in a number of insightly scars and impacts. Our
6 question to C. P. Rail is are they committed and
7 prepared to maintain the integrity of the construction
8 area even if construction may be delayed? This is
9 an important point and should be addressed by both
10 C. P. Rail and the Panel.
11

12 The third area of concern is that
13 of Visual Impact Assessment. We find the Visual
14 Impact Assessment study deficient in a number of
15 areas. The study was limited to evaluating the
16 visual impacts of the project on users of the Trans
17 Canada highway. While the authors acknowledged
18 the fact that many trails exist in the park and
19 around Glacier House which attract climbers and hikers
20 from around the world, no attention was paid to the
21 visual impact on trail users. What are the
22 implications of this project on backcountry users?

23 Many assumptions have been made
24 about how visitors perceive the Park as it
25 presently exists and how the project will be viewed.
26 Upon what evidence have the authors drawn to make
27 their conclusions?

28 The monitoring program referred
29 to by the authors and C. P. Rail in its June, 1983
30 document is not to be found. While mention is later

(Cockerton)

1 made by C. P. Rail of a monitoring program on page
2 L06, the monitoring is only periodic. Are 14 site
3 visits by the landscape architect sufficient?
4

5 Finally, the report seems to
6 under-estimate the size of the cuts and fills.
7 While early indications were that they were to
8 be confined to 200 feet, we find discussion of cuts
9 that are almost 600 feet.

10 The fourth area of concern is that
11 of Work Camps. Parks Canada has requested C. P.
12 Rail to withdraw their proposal to locate work camps
13 within Glacier National Park. The Association
14 strongly supports Parks Canada in its position.
15 National Parks are established to:

16 (1) protect and manage the
17 natural environment and also

18 (2) provide outdoor recreation
19 opportunities as a means to understand and enjoy
20 heritage resources.

21 The establishment of work camps
22 within the Park are clearly contravening this
23 policy. We do not accept the position that
24 work camps of the size proposed, located in the Park
25 for at least four years, will not attract bears.
26 Furthermore, despite the recommendations of Doctor
27 Stephen Herrero, based on his work as submitted to
28 C. P. Rail, C.P. Rail has decided not to adopt
29 his recommendations on economic grounds. I might
30 say that based on what I have heard earlier this

1 (Cockerton)

2 evening that may not be quite an accurate
3 representation.

4 It is our opinion that C. P. Rail
5 is proposing a situation here where a number of
6 contacts between workers and bears will be possibly
7 fatal to both. Ultimately, a number of grizzly
8 and black bears would be destroyed.

9 Also, while the discussion has focused
10 on the interaction of bears and workers, no attention
11 has been paid to the possible problem that bears
12 attracted by the camps will have an impact on
13 park visitors and backcountry users. In short,
14 the cumulative effects of site disturbance, loss
15 of park facilities, aesthetics, social problems,
16 wildlife conflicts, and other environmental problems
17 lead us to believe the work camps should be outside
18 the Park.

19 On the economic aspects, why is
20 C. P. Rail paying double-time for travel? Why
21 should the Park be penalized for conditions that exist
22 between C. P. Rail and the unions?

23 In conclusion, we congratulate
24 all involved for the establishment and use of the
25 committee system. It is our understanding that
26 they have been effective in the decision-making
27 process. We strongly urge that these committees
28 and that members participate fully so as to ensure
29 the proper design and construction of this important
30 railway corridor as well as the prevention and

(Cockerton)

1 mitigation of impacts.

2
3 Finally, the National and Provincial
4 Parks Association fully acknowledges the fact that the
5 Canadian Pacific Railway has been a part of the
6 visual and cultural heritage of Glacier National
7 Park for the past 100 years. We have no doubt that
8 future generations will view the construction
9 that will occur at Rogers Pass in awe. But C. P.
10 Rail must view Rogers Pass and the twinning
11 of the rails in its proper perspective: the primary
12 reason for establishing a national park here was the
13 scenic and beautiful landscapes.

14 Environmentally sensitive management
15 techniques will no impress the public, nor will
16 people stare in awe at this railway corridor if large
17 slope failures, eroded hillsides and polluted
18 rivers scar the landscape when the project is
19 completed. The public will know these scars are
20 the result of a poorly constructed railway.

21 The authors of the Visual Impact
22 Assessment are confident that people will view
23 this project as a wondrous undertaking. We do
24 not share their optimism.

25 The task ahead is difficult. We
26 realize that all the damages cannot be predicted,
27 nor fully mitigated. Frankly, though, we would
28 find it somewhat reassuring if C. P. Rail stated
29 that it will commit the time, the resources and
30 the money to reclaiming Rogers Pass on a scale

(Cockerton)

1 that is similar to the effort that they are
2 placing into the construction phase of this
3 project. Thank you.

4 THE CHAIRMAN: Panel, do you have
5 any questions?
6

7 DR. ROSS: Mr. Cockerton, you
8 mentioned or I guess questioned whether the 14
9 site visits by the landscape architect would be
10 sufficient. Are you suggesting that more are
11 necessary; that continuous presence of a landscape
12 architect or reclamation consultant or inspector
13 are required?

14 MR. COCKERTON: I have to assume
15 that what was meant by the remark is that a given
16 number of site visits would probably not in itself
17 be adequate. Perhaps it was the only reference
18 found by Mr. McNamee to the kind of monitoring
19 measures that C. P. Rail had proposed to ensure
20 that visual management techniques were effectively
21 applied during the construction period.

22 THE CHAIRMAN: C. P. Rail do you
23 have any questions you wish to ask?

24 MR. FOX: I would just like to ask
25 the gentleman what is your professional background?

26 MR. COCKERTON: My professional
27 background presently is as a recreation planner.

28 MR. FOX: Thank you very much.
29 No further questions.

30 THE CHAIRMAN: Parks Canada?

DOCTOR LEESON: No questions.

THE CHAIRMAN: Do any members
of the audience have any questions on this
presentation? -- If not, I think at this
point I would like to thank you for coming along
to make presentation on behalf of the M.P.P.A.C.,
and I think that this time might be appropriate
to call a break and have some coffee before we
get back to the issue of camps.

---Brief adjournment.

D-1

1 ----Upon Resuming

2 THE CHAIRMAN: If we can all take
3 our seats again, please, we will reconvene.

4 I have short announcements here,
5 one of which is that there is an overlay apparently
6 being prepared of the area of the works camps, has
7 been prepared, and it is available for people to
8 see at the back of the hall when you want to.

9 We are going to go back to the work
10 camps again where we left off. One thing I would
11 like to clarify and get on the record. Mr. Tikkanen
12 from CTC, I wonder if you could inform us concerning
13 the existing right-of-way that Parks or that C.P.
14 has as to if there are any deviations from the
15 200 feet or 275 or wherever they have it, what is
16 required? As I understand it, that is an approved
17 book of reference by the CTC and that CTC would have
18 to approve any changes.

19 MR. KEN C. TIKKANEN (Canadian
20 Transport Commission): That is quite right. Mr.
21 Chairman. The CTC approval has been given to specific
22 planned profile book of reference, and if there is
23 any deviation from that then there would have to be
24 a reapplication by the railway.

25 THE CHAIRMAN: I presume you would
26 not have to go through a whole hearing process again?
27 You would just ask the various parties if they were
28 in agreement?

29 MR. TIKKANEN: Exactly.
30

D-2

1 THE CHAIRMAN: I guess, then, we
2 will go back to work camps, and Panel, do you have
3 any further questions you would like to ask? Bill
4 Ross.

5 DR. ROSS: I guess this question is
6 for Mr. Fox or Mr. O'Neill. It deals with the odour
7 problem. I was not sure what your odour control
8 mechanism proposed was, Mr. Fox. In particular, I
9 was inquiring about whether you were planning to
10 use any fume incinerators?

11 MR. O'NEILL: The control of the
12 odours would be two-fold. We would be putting charcoal
13 scrubbers on the food that comes from the cooking area
14 and it has been recommended to vent higher the
15 stacks, then you would be putting a larger horse-
16 power motor on the stack to throw the air up.

17
18 Around the garbage area, which is
19 common, is very heavily Pinesolled and mothballed.
20 Not everybody uses mothballs. I am not sure how
21 many people know, but I swear by them, even in my
22 own back yard, to be truthful I have bears.

23 DR. ROSS: That is one of your
24 own secrets, is it?

25 MR. O'NEILL: Yes. So really, those
26 odours of cooking do not draw in anywhere near as
27 much as the garbage odour. That is the odour that
28 if it is not controlled is the problem.

29 DR. ROSS: I see. Dr. Herrero,
30 I guess you made reference to a team of bear experts.

D-3

1 Sorry, a team of experts dealing with bear problems --
2 let me ask a different question.

3 Monitoring. Presumably you would
4 expect that a difficulty such as this would have
5 a monitoring component of it, whether that team of
6 experts would be involved or not. What would likely
7 consist of an appropriate monitoring program and
8 an evaluation program?

9 DR. HERRERO: First of all, I would
10 underline what you have just said. I think
11 monitoring would be a very important component of it
12 because this is one of those areas where you can
13 only so, I think, anticipate 70 or 80 or perhaps 90
14 percent of the problems, but some of them have to
15 be responded to as they develop. Perhaps, let us
16 say, ingress and egress from the gate. If a full
17 perimeter fence is not adopted, then there are, I
18 would see problems of controlling ingress and egress
19 and making sure the gates are closed and things.
20 That is just an example of a minor problem which can
21 have major consequences for bears or people if it
22 is not attended to.

23
24 Now, most of these situations I
25 would imagine the environmental coordinator would
26 be on top of. He has a background and history in
27 dealing with bear problems in parks, but there are
28 certain situations, perhaps at the design phase or
29 in the redesign or retuning of the fencing that I
30 think having the expert advice of people who have

D-4 1 worked with similar situations and worked with
2 bears for a number of years would probably be
3 desirable. So I think the day-to-day monitoring is
4 certainly the responsibility of the environmental
5 coordinator.

6 However, I think the desirability
7 of having a team of experts familiar with these
8 problems who look at it maybe two or three times in
9 the design phase as it starts to go to working
10 drawings and then look at the camp a couple or three
11 times a year, especially if problems are developing
12 but perhaps even more so to keep them from developing,
13 that is what I had in mind.

14 DR. ROSS: I guess that leads me
15 to the next question which is to seek your best
16 professional judgement on the difference between the
17 full fencing and the partial fencing proposed in
18 the red book here. I assume from your original
19 report you would recommend the full fencing and
20 you indicated that you were unsure, if I understood
21 you correctly, of the likely success of the partial
22 fencing. Have you got anything more that you would
23 care to elaborate on that difference?

24 DR. HERRERO: Thanks. There are
25 several factors which make me still and perhaps even
26 more strongly so favour the full perimeter fencing
27 if the camps -- well, I would favour it no matter
28 where the camps are built, but especially if they
29 are built in the Park site locations, I strongly
30

D-5

1 favour it, and that is because the camps will,
2 as I have previously said and Mr. Fox has previously
3 said, pretty well make use of the available site
4 so that there really will not be a cleared perimeter
5 around the outside of the camp.

6 Now, this means that bears can use
7 the forest as cover and approach closely to the
8 camps. From there, it is only a matter of 30 feet
9 at the most. Let us say the 30 foot perimeter is
10 maintained for snow clearance, it is a matter of 30
11 feet for a bear to come in and explore the camp.
12 Now, if worse comes to worse, and I am sure it would
13 be worse to worse, and you know, a worker throws
14 a sandwich out the window or they are sitting around
15 drinking beer one afternoon and they leave a couple
16 of bag of cheesitz out and grizzly bear happens to
17 come into camp and a worker happens to go out that
18 night and bump into it, it could lead to a serious
19 injury; it could lead to a minor injury as well.

20 But the full perimeter fence
21 precludes that possibility of occurring within the
22 perimeter and one of the principles I have come to
23 feel is very, very important, over the years in sort
24 of designing areas for bears and people is that
25 campgrounds really ought to be, or camping areas or
26 living areas really ought to be areas for people,
27 not areas where people and bears are mixed up.

28 The advantage of the full perimeter
29 fence is there is no uncertainty as to whose territory
30

D-6

1 is whose. Outside the fence it is the bears; inside
2 it is the peoples. Even though the design of the
3 camp has corridors, enclosed corridors which the
4 workers could pass through, I still suspect they
5 would spend enough time outside that, you know, some
6 food or garbage could accumulate and workers would
7 walk around the camp and would assume it is their
8 area but that would not necessarily be true.

9 With the full perimeter fence it
10 would be true.

11 THE CHAIRMAN: If I could follow
12 up on that, I believe that part of Mr. Fox's argument
13 was that he felt that by putting a fence up, a
14 full perimeter fence it would be treating that work
15 area differently from other areas in the Park, and
16 maybe you could tell me why you think that a
17 campsite area is different as opposed to a campsite
18 where people are pulling up with their tents and
19 possibly leaving out their cheese sandwiches or
20 whatever? Is it because those sites are particularly
21 grizzly bear habitat as opposed to the campsites
22 that tourists use? What is the difference between
23 the two sites that requires a full perimeter fence?

24 DR. HERRERO: I suppose the first
25 thing that brought it to my mind was the magnitude
26 of the operation. At the time I had assumed that
27 it was for 250 people and now we know it is for over
28 400 people. The intensity of the operation and
29 the amount of food and throughput of food and garbage
30

D-7

1 is quite substantial. I frankly do not know the
2 extent to which other large campgrounds such as
3 Illecillewaet, the number of people there and the
4 volume and throughput of garbage, I know in general
5 Glacier has managed its garbage very well. They
6 have bear-proof storage of garbage and they seem to
7 be able to convey the message to people to keep
8 their food under good storage. Glacier has not had
9 many problems with bears in campsites.

10 As you go out to the east and down
11 into the black bear areas more, there have been
12 a lot more black bear problems, however, in campsites
13 there, and I am not sure what has happened to the
14 west. I am not familiar with the camping areas that
15 are there.

16 But I am not sure to the extent to
17 which the situations are analogous and when I say I
18 am not sure, I am not sure, and I regard it as an
19 important question. It may be that the volume of
20 garbage and food handled and processed by the C.P.R.
21 camps is analogous to a similar campground. I do
22 not think so. I think the C.P.R. camps are a bit
23 more substantial.

24 There is no question in my mind in
25 both situations, though, that the overall population
26 densities of both species of bears, both black and
27 grizzly bear in Glacier Park as a whole with some
28 areas being favoured by grizzly bear, for example,
29 around Flat Creek in the potential Glacier campsite,
30

D-8

1 and other areas being more favoured by black bear
2 down around Beaver camp, but there is no question in
3 my mind that the potential for bear problems exist
4 in all these operations because the density of
5 bears is a relatively high one.

6 So I am not sure if C.P.R. -- you know,
7 it seems to me to be a potentially important argument
8 that they may be being forced if the camps were in
9 the Park to perform to much higher standards, and
10 I think it would require a more careful look and
11 a more detailed understanding of the current
12 operations at the Northlander for Parks Canada and
13 the various campgrounds than I have right now to be
14 able to evaluate that argument.

15 THE CHAIRMAN: Do Parks have
16 anything they want to add to that question that I
17 put out?

18 MR. TENCH: Does anyone know what
19 does happen at the Northlander that will give us an
20 idea of how they treat their garbage and how they
21 protect things there?

22 MR. GALLACHER: We take care of
23 their garbage, as we do their whole camp, and we
24 have not had any difficulty whatsoever and we do not
25 have fences.

26 DR. HERRERO: How do they store
27 their garbage?

28 MR. GALLACHER: It is stored in
29 containers, above ground containers and we remove
30

D-9

1 the garbage once daily.

2 DR. HERRERO: These are bear-
3 proof containers?

4 MR. GALLACHER: That is correct.

5 DR. HERRERO: And there is no
6 history whatsoever of any bears being captured at
7 those sites?

8 MR. GALLACHER: None to any great
9 extent.

10 DR. HERRERO: Does that mean there
11 is some then?

12 MR. GALLACHER: There are some,
13 yes.

14 DR. HERRERO: Thank you.

15 MR. GALLACHER: But that is operated
16 365 days a year, 24 hours a day during the winter
17 months.

18 DR. ROSS: I guess my last question
19 for you, Dr. Herrero, deals with the relative impact
20 on Park bears of campgrounds inside versus outside
21 the Park. Do you expect that there would be much
22 difference in terms of bear problems if the camp
23 were inside versus outside the Park?

24 DR. HERRERO: The locations being
25 proposed are close enough to the Park that they
26 come within the home range of Park bears. The bears
27 do not respect the boundary lines terribly well.
28 So a poorly managed camp outside of the Park, in
29 terms of the potential for generating problems, I
30

D-10

1 think could be almost as great as a -- well, it would
2 be worse than a well managed camp within the Park
3 from the bear point of view. From the bear point
4 of view only I have, you know, complete faith in
5 the full perimeter fencing as a solution along with
6 control of workers' activities and the other factors
7 I mentioned in keeping the problem well under
8 control.

9
10 Outside, the Province of B.C. does
11 not quite have the same environmental management
12 standards as Parks Canada does, and it is my
13 impression, and Fish and Wildlife in B.C. could
14 correct me if I am wrong in this, that they are
15 much more want to use the rifle as a solution to
16 bear problems than Parks Canada is.

17 I know this has been the case at
18 Quintet Coal, one of the camps that has been
19 previously mentioned in the Northeast Coal Block
20 because a biologist colleague of mine was hired last
21 fall to deal with extensive black bear problems which
22 developed there, and he reported to me in writing
23 that he killed between eight and ten black bears
24 merely to provide for human safety in and around the
25 camp.

26 Now, I am not suggesting that that
27 would be an analogous situation which would
28 develop in Glacier Park, but merely to point out
29 that the regulations in B.C. are a little different
30 in terms of treating nuisance animals or animals made

11 1 to be a nuisance than they are in Parks Canada.

2 So I am really of two minds about
3 the whole thing. I think really from the bear point
4 of view only a very well managed and designed and
5 operated camp inside might be the ideal. Outside,
6 of course, if they would manage it to the same
7 standards then especially to the west you do get a
8 little bit more out of grizzly bear habitat. There
9 still is grizzly bear habitat and grizzly bears as
10 you go further to the west, but you start to get
11 a little bit away from the center of action.

12 So from the habitat point of view
13 you would probably get a bit of improvement by
14 going further to the west.

15 With regard to the east camp and
16 going further to the east, you are in black bear
17 habitat with a few grizzly bears and you continue
18 to be in black bear habitat with probably a few
19 grizzly bears so you do not get much of a habitat
20 change by going the distance to the east.

21 DR. ROSS: Which leads me to my
22 next question for Mr. Fox, which is would you plan
23 to construct and operate the work camps in the same
24 fashion at either of the sites, inside or outside
25 of the Park?

26 MR. FOX: I think so far as
27 regards to where the camp is. it will be built and
28 maintained to the same standard and operate to the
29 same standards.
30

D-12

1 DR. ROSS: Thank you. My next
2 question again for Mr. Fox, Dr. Herrero suggested
3 removing the fence in the winter from December to
4 April. You seem to have rejected that as a solution.

5 MR. FOX: No, I have not rejected
6 it as a solution. It is just another added expense
7 you have to worry about. You have to store the
8 fence. You can have it constructed in panels. You
9 can have larger diameter pipes sunk in the ground
10 and put the vertical posts or the panels in there
11 and bolt it in place and this sort of thing. That
12 can be done, but you know, when you are dealing with
13 something in the order of a quarter of a mile of
14 eight foot high chainlink fence with a barbwire
15 top and electrification on it, it is not a small
16 job to remove that and erect it twice annually.

17 It is just more money, more cost,
18 and of course, if you are taking a fence down and
19 erecting it twice a year, you are apt to damage it
20 and you have got repairs, and if repairs are not
21 made, well, you have not got the security, so you
22 know, that is the sort of thing you will run into.

23 DR. ROSS: In the Flat Creek camp
24 when we were there on our site visit yesterday, I
25 believe, it seemed to me that the camp was essentially
26 surrounded by some rather tall trees?

27 MR. FOX: That is right.

28 DR. ROSS: In order to provide
29 access for snow clearance around the outside of that
30

D-13

1 fence, would you either clear those trees or would
2 you reduce the size of the camp inside the fence?

3 MR. FOX: The camp size cannot be
4 reduced. We have put it down to the smallest
5 scale we have. There are certain regulations you
6 have to follow.

7 For instance, in terms of how far
8 the buildings have to be apart for fire protection,
9 you have to have a fire road around the buildings
10 and things of that nature, so you know we have got
11 them right to the minimum according to the law,
12 and we have done a lot of things really. The
13 actual camp size, and I guess this has not been
14 explained at all, the actual camp size has not
15 increased from what we proposed last year. What we
16 have done, we have double-decked everything.
17 So the actual area has not increased one square foot.
18 That is how we have solved that problem.

19 DR. ROSS: But that means if you
20 were forced to choose between, in terms of
21 maintaining the fence and were precluded from cutting
22 down those trees, for example, then you would
23 essentially be forced to remove the fence for the
24 winter.

25 MR. FOX: That is probably the
26 only solution to the problem, as I see it, to get
27 away from the snow.

28 DR. ROSS: Thank you.

29 DR. HERRERO: Could I comment?

DR. ROSS: Please do.

DR. HERRERO: I did not really suggest that the fence should be removed. I identified it as one possibility that might be looked at. I really do not know about the engineering feasibility of that type of situation.

DR. ROSS: I understood that. It did not seem to have been raised again and I wondered why. I understand, I think, now.

Mr. O'Neill?

MR. O'NEILL: In all fairness to the operation at Quintet and the bears that were removed in Quintet, they had a bear problem in Quintet because they originally located the dump within a stone's throw of the camp. That dump has since been removed ten miles away, has been fence and there is no further bear problems, to the best of my knowledge. It was the garbage drawing the bears in.

DR. ROSS: Parks, I believe in Revelstoke you made some suggestion that you had reason to doubt the figure of \$33 million of extra transportation cost. I wonder if you would care to pursue that at this time? In fact, I believe you promised to raise the issue at a later date in the hearings.

DR. LEESON: I think it was Mr. McCrory who specifically brought it up in his presentation.

D-15

1 However, we also have similar
2 concerns. For example, the timing indicated in the
3 red book to get to the camp is a lot more than we
4 have timed it. It is nine kilometers and at highway
5 speeds in a pickup truck it was six minutes from
6 Flat Creek to the turnoff down to the other one,
7 about 13 minutes to get down through the very rough
8 road to the Illecillewaet camp which is substantially
9 less than what is being proposed here.

10 We also have our own concerns
11 about simply doubling the overtime because it seems
12 to us there are some costs that would not be doubled
13 and we would recommend to the Panel to request
14 quite a detailed breakdown of that figure to see
15 if ---

16 DR. ROSS: I guess this is my way
17 of starting to ask that, and I can see Mr. Fox is
18 turning to his figures, so I guess he is anticipating
19 my next question, which I guess I might just as
20 well make. Mr. Fox, would you ---

21 MR. FOX: Well, first of all, I
22 would like to question the 13 minutes. Sure you can
23 do it in 13 minutes, I can do it in 13 minutes,
24 you can even do it on that motorbike of yours, but
25 you are doing 90 kilometers an hour.

26 These people are travelling in the
27 equivalent of a school bus with up to 40 men in it
28 and you are going up grade when you are going to
29 the work site. Now, how long is it going to take you?
30

D16

1 It will take you what I said. That is the
2 difference. You cannot go by what your motorbike
3 tells you, Mr. Leeson, or what I can do in my
4 automobile or whatever. We timed it too at 13
5 minutes.

6 Another factor that we have not
7 brought into our figures is how long is it going to
8 take a bus like that to get across the railway
9 tracks. And you were all there yesterday and you
10 saw what I did. I got out of my vehicle and I
11 flagged you people across. That is another thing
12 that is not in these costs and that is something that
13 would have to be done. You can face up to 15 to
14 20 minutes delay there pretty well any time if
15 trains are meeting at that point because they block
16 that crossing. Those are not in the figures.

17 So those are some of the other
18 things that have to be considered at that site.

19 Now, how did I arrive at this?
20 The hourly rate for a miner is \$19.71 an hour. This
21 is straight time. To that, and this is what C.P.
22 is going to pay for, to that I have to add 37 percent
23 overhead that the contractor has. To that I have
24 got to add 15 percent for supervision, and this is
25 what I am going to be charged with. Then I have got
26 to add an overhead figure of ten percent; then he
27 wants a profit on that, 20 percent.

28 So the hourly straight time cost to
29 me is \$40.99. The union agreement under which these
30

D-17

1 people work states that all travel time will be
2 paid at double time. So I double the \$40.99 and I
3 get my \$81.98 an hour.

4 Now, to work out your manhours of
5 the people who are working there and multiple it
6 out for the four years that we are going to be there,
7 you are looking at \$33 million. It is a simple
8 matter of arithmetic.

9 Another factor in there, for every
10 15 minutes of travel time, they get paid 30 minutes
11 time. So if they travel for 15 minutes, they get
12 30 minutes double time; if they travel 60 minutes
13 they get an extra 30 minutes, and that is what
14 really crunches it.

15 I cannot do anything about that
16 because that is a signed agreement that the
17 contracting people have with the unions.

18 If you like, I can give you a
19 detailed statement on it.

20 DR. ROSS: I think you just have.

21 THE CHAIRMAN: George Tench, any
22 questions?

23 MR. TENCH: No.

24 THE CHAIRMAN: Parks Canada, do you
25 have any questions?

26 DR. LEESON: No, thank you.

27 THE CHAIRMAN: Any members of the
28 audience that wish to raise any questions on work
29 camps?

We are now going to move to another issue which I believe C.P. Rail you have a couple of consultants who you mentioned earlier on today. It is not specifically listed in our agenda, but there is a couple of items that we still have to cover and now seems to be an appropriate time if you would like to do so.

MR. FOX: Thank you very much, Mr. Chairman. There is only one consultant to give a talk but he will talk on two subjects. It is Dr. Hollibaugh from MacLaren Plansearch, and the subjects are erosion to aquatic habitat and waste water treatment, and I understand it is something of a 20 minute presentation; is that right, Tim?

MR. HOLLIBAUGH: One of them is 20 minutes; the other one will be 20 minutes as well.

D-19

1 (Hollibaugh)

2 MR. TIM HOLLIBAUGH (MacLaren
3 Plansearch): Mr. Chairman, Panel members, ladies
4 and gentlemen, in response to concerns expressed by
5 Parks Canada, C.P. Rail requested MacLaren
6 Plansearch to investigate the potential impacts of
7 erosion on downstream aquatic environments during
8 construction of the Beaver Valley surface route.

9 The terms of reference of this
10 study were agreed upon during a meeting with Dr.
11 Leeson in 1982. The study was to determine those
12 habitats most susceptible to impact by material
13 that might be eroded off the right-of-way and to
14 recommend a program to monitor these habitats to
15 decrease the risk of habitat degradation. This
16 presentation summarizes the results of that study.

17 Basically there are two different
18 kinds of aquatic habitats in Beaver Valley. One is
19 a stream habitat represented by Beaver River, Connaught
20 Creek, Stoney Creek and Mountain Creek and the
21 other creeks crossing the right-of-way. The second
22 is the pond the marsh habitat represented by
23 the numerous beaver ponds found in the flats of the
24 Beaver River floor plain.

25 Our study investigated both of
26 these habitat types. Of the two, we found that the
27 marsh and pond habitats were probably the most sensitive
28 to potential disruption by construction on the right-
29 of-way, both because they were adjacent to the
30

1 (Hollibaugh)

2 right-of-way and also because they have a decreased
3 ability to rid themselves of sediment because of the
4 slow flow rates of water through these areas.

5 The rest of this discussion will
6 focus primarily on the marsh and beaver pond
7 habitats, although I will make some comments on
8 fishery resources of the Beaver River later on in
9 the presentation.

10 The Beaver pond habitats in the
11 Beaver Valley are very important for a number of
12 reasons, some of which are summarized on this slide.
13 They provide resting and feeding habitat in the
14 Park for migrating water fowl and shore birds,
15 nesting in rearing habitat for some water fowl and
16 shore birds. They are a primary habitat for
17 beavers and muskrats, of course. They also provide a
18 significant hunting habitat for semi-aquatic fur
19 bearers such as otter and mink which prey on the
20 beavers, muskrats, birds and so on, and they are
21 also a spring feeding habitat for bears, a breeding
22 habitat for at least four species of amphibians and
23 they provide forging opportunities for moose.

24 Some of the ponds also contain
25 significant population of fish species not found
26 in any abundance in the Beaver River or its major
27 tributaries.

28 This slide shows the area sample
29 by MacLaren Plansearch field personnel during a fall
30

1 (Hollibaugh)

2 survey in 1982. The study concentrated on examining
3 fishery resources in the Beaver River and its
4 major tributaries, and some of the beaver ponds.
5 Wildlife biologists determined the locations of
6 active beaver ponds in the Beaver Valley and their
7 relationship to streams crossing the right-of-way.

8 We also examined the amount of
9 sediment transported by the various streams in the
10 Beaver Valley, the areas where the sediment was
11 being deposited at present and areas where the
12 sediment derived from potential erosion on the
13 right-of-way might be expected to be deposited.

14 In addition to the field studies,
15 we determined the extent of watershed of the
16 creeks crossing the right-of-way using topographic
17 maps and mapped these watersheds in relationship
18 to the resources in the Beaver Valley.

19 Watersheds are shown in the following
20 slide. It can be seen that most of the watersheds
21 of these streams crossing the right-of-way lie well
22 above the right-of-way and that where the streams
23 cross the right-of-way there is only a limited amount
24 of area draining directly into the stream beds. Most
25 of the right-of-way area would drain directly
26 downslope from the right-of-way into habitats below
27 the right-of-way.

28 In these areas, sediment derived
29 from erosion would be spread over larger areas.
30

1 (Hollibaugh)

2 Sedimentation would not be concentrated, as it
3 might be, if all the sediments were emptied into
4 the streams crossing the right-of-way. Sedimentation
5 may be concentrated somewhat by smaller intermittent
6 streams crossing these areas which are not shown on
7 this map. However, cross slop draining by
8 ditching along the right-of-way or by benching out
9 of cuts, as has been suggested earlier today, might
10 cause increased sediment deposition or might cause
11 an increased amount of the sediment to enter the
12 streams if these ditches or whatever drained into
13 the streams.

14 Beaver habitats in the Beaver Valley
15 were mapped during an extensive field program last
16 fall. An example of the map produced is shown
17 in the following slide. You can see that the beaver
18 areas were classified as to active and inactive
19 systems. I do not know if there are any inactive ones
20 on that slide, and the number of colonies in each
21 area was determined by counting the number of food
22 caches from a helicopter survey. Incidental
23 observations on the occurrence of other wildlife were
24 also made.

25 Further information was obtained,
26 further information on organisms and animals in the
27 Beaver Valley was obtained in discussions with
28 Canadian Wildlife Service in the Park and by
29 reference to unpublished manuscripts produced by
30

1 (Hollibaugh)

2 the Canadian Wildlife Service.

3 This slide shows the area roughly
4 between the road down to the gravel pit bridge,
5 which is kind of off the slide to the left, and
6 Stoney Creek. Three creeks cross the right-of-way
7 in this area: Tupper Creek, an unnamed stream on
8 this map which is also known as Soper Creek, and
9 Stoney Creek.

10 The second slide shows the area
11 further downstream including Stoney Creek, two
12 avalanche chutes and Surprise Creek, and the
13 habitats downstream of these environments or the
14 habitats downstream from here. You can see that we
15 did not just concentrate on beaver habitats between
16 the Beaver River and the right-of-way, the area
17 which is expected to be impacted by the construction
18 of the right-of-way. It included all the habitats
19 in the Beaver Valley since these are also important
20 in providing recruits to habitats on the other side
21 of the Beaver River.

22 In all 17 areas of beaver activity
23 were observed in the Valley. In most cases there
24 was only one colony per area, but in some cases
25 there were two or more colonies. Our wildlife
26 biologist was then asked to rank the susceptibility
27 of the areas with respect to potential impact from
28 erosion based on his knowledge of the area and a
29 location of the beaver systems with respect to streams
30

(Hollibaugh)

crossing the right-of-way. The ranking produced by the biologist is shown in this slide. As you can see, there are three areas with moderate to high susceptibility to erosion occurring on the right-of-way. These areas are located on Tupper Creek, on Soper Creek, which is referred to as the unnamed stream as unnamed stream number 3 in our report, and the avalanche paths which are referred to as unnamed streams numbers 5 and 6 in the report which we tabled with the Panel. Other habitats in the Beaver Valley were identified as having low to moderate susceptibilities or no susceptibility at all.

A hydrologist involved in the study was next asked to draw profiles of the streams crossing the right-of-way and to indicate on these profiles the beaver areas and also where he might expect sediment removed from the right-of-way to be deposited. Examples of this analysis are shown on the next four slides.

The first gives a profile of Tupper Creek showing the two beaver activity areas located downstream of the right-of-way and the areas where sediment might be deposited. We have indicated areas of deposition of both coarse and fine sediment by the different sizes of the dots.

As you can see from looking at these slides, the slope above the activity area is

1 (Hollibaugh)
2 extremely steep and the slope changes abruptly as
3 it reaches the Valley floor. The flat area in
4 the Valley floor will be expected to collect any
5 sediment being removed from the right-of-way by
6 erosion.

30

PM-E-1

(Hollibaugh)

The next slide, a profile of Stoney Creek. You see that there are no flat areas downstream of the right-of-way and that the slope where the stream crosses the right-of-way is fairly moderate. In addition there are no beaver activity areas located on Stoney Creek. This partly because of the steepness of the creek, the high grading of it, which makes it difficult for them to maintain dams and the fact that there is very forage material for them on this stream.

The profile of Stoney Creek is typical of the three major streams crossing the right-of-way, Connaught Creek, Stoney Creek and Mountain Creek. They all have a fairly high slope which is continuous all the way to the Beaver River, and the velocities at which the water crosses the flood plain would not allow finer sediment to be deposited before they reach the Beaver River.

The last two examples are the streams crossing the avalanche paths which were referred to in the report as unnamed streams number five and six. As with Tupper Creek, you can see that the slopes above the valley floor are fairly steep. Where the streams cross the right-of-way they still have a high gradient which decreases abruptly as the streams reach the valley floor. You will also notice that there is indication of debris cone in this stream by the decrease in slope relative to the high slope of Tupper Creek,

PM-E-2

1 (Hollibaugh)

2 which does not have a debris cone. As you can see
3 in the figures sediment will be deposited where
4 these streams begin to flatten out and on both
5 of these streams there are beaver areas that
6 might be impacted by this deposition.

7 The final step in our analysis
8 was to go to aerial photographs and topographic
9 maps to try and map the areas where sediment would
10 be deposited with respect to specific habitats.
11 Examples of this analysis are shown in the next
12 two slides. This slide shows the area downstream
13 of Tupper Creek, which is off to the left over
14 here, and Soper Creek, which is off to the left
15 over there. As you can see most of the sediment
16 crosses the Trans Canada highway in Tupper Creek
17 would be deposited in the alder thickets above
18 the beaver pond before it reached the pond. Below
19 Soper Creek there are presently beavers working
20 in the area right below the Trans Canada highway.
21 Some of the sediment would probably be deposited
22 in these areas. Finer sediment would reach the
23 pond at the lower center of the photograph on
24 Soper Creek and probably also this pond on Tupper
25 Creek.

26 The next slide shows the area
27 below unnamed streams number five and six and in
28 the avalanche path and also Surprise Creek. This
29 is an extremely complicated area with respect to
30

1 (Hollibaugh)

2 beaver activity, but again you can see that most
3 of the sediment will be deposited before it
4 reaches the ponds and the alder bushes at the
5 margin of the ponds. However, some of the finer
6 sediment would be expected to reach the ponds.

7 Sediment might be deposited in
8 the foraging areas below Surprise Creek. Up in
9 this area we found beavers that had pushed up
10 into the coniferous forest and were taking down
11 cottonwoods well above where their lodges and
12 wintering ponds were. This situation was observed
13 at both Surprise, Raspberry and Cedar Creek.
14 The sediment on Surprise, Raspberry and Cedar
15 Creek probably would not reach any of the ponds
16 themselves.

17 To go back to the stream habitats,
18 the results of our surveys of the stream habitats
19 revealed an extremely impoverished fisheries
20 resource. We obtained samples of three species
21 of fish: Dolly Varden or bull trout, mountain
22 white fish, which was the most abundant species,
23 and slimy sculpin. We could not find any spawning
24 areas, however potential spawning areas were located
25 above the gravel pit bridge and possibly in the
26 mouth of Stoney Creek and possibly near the
27 Mountain Creek campground bridge. We found young
28 fish in the river indicating that there had been spawning
29 activity but again these were very few. A few of the
30

1 (Hollibaugh)

2 streams were marginal habitats for fish because
3 of the fast flow rate of the water, the cold
4 temperature and the high sediment loads carried
5 by the streams from glacial flower and erosion
6 along the tributaries.

7 The only significant fish resource
8 we did find were in beaver ponds located between
9 Cedar Creek and Surprise Creek, which contained
10 an extremely abundant population of extremely
11 small brook trout. We feel that these fish were
12 overcrowded and probably underfed.

13 Our final task was to recommend a
14 monitoring program capable of detecting potential
15 problems so that mitigative and preventative
16 measures could be implemented before the problems
17 really developed.

18 The final slide indicates the kinds
19 of monitoring we suggest. At the time that
20 we wrote this report we do not have a specific
21 program of measurements, frequency and what-not
22 in mind but the kinds of things that one would
23 expect to be doing are listed on this slide.

24 Streams crossing the right-of-way
25 should be inspected on a regular basis daily or
26 more frequently to look for changes in the colouring
27 of the stream as it crosses the right-of-way since
28 the colour of the water is the best reflection of
29 sediment content available. It also gives an
30

1 (Hollibaugh)

2 instantaneous result, which is very important
3 because in methods employing laboratory analyses
4 you often wait two to three days to get the results
5 back from the laboratory to confirm something
6 which you can see with your eyes, and if you wait
7 that long to take mitigative measures, you will
8 greatly increase the impact.

9 Periodically, however, these
10 evaluations should be checked against actual
11 determinations of sediment loads in the streams,
12 particularly in those streams influenced by glacial
13 flower. Sediment depositions in the environments
14 downstream should also be monitored, probably by
15 using a survey technique that would detect lower
16 but more constant levels of sedimentation.

17 The activity of the animals in
18 the habitats below the right-of-way should also
19 be monitored to indicate whether they are being
20 disturbed either by sedimentation or by activities
21 on the right-of-way. The terrestrial environment
22 should be examined periodically for sediment
23 deposition to see if sluffing or what-not is
24 occurring on the slopes. This will probably be
25 evident from examination of the slopes themselves,
26 and it would be important to keep track of how
27 far any sedimentation is occurring -- is penetrating
28 into the forest below the right-of-way, and by
29 knowing this to take appropriate measures to stop that
30 activity.

(Hollibaugh)

1 I have listed down here some of
2 the kinds of mitigation measures that one could
3 utilize. There are many more available and
4 possibly someone more familiar with the kind of
5 measures to control erosion on slopes like this
6 would be more qualified to speak on the actual
7 techniques are used, but these are some that I
8 thought of in examining the data that we obtained.
9

10 I thank you very much and I
11 would be happy to answer any questions the Panel
12 or the audience might have on this particular
13 presentation.

14 MacLaren Plansearch was also
15 asked to identify potential sources of water for
16 use in tunnel construction and to investigate the
17 design and siting of treatment facilities for
18 tunnel effluent in the Rogers Pass area. In the
19 next few minutes I will present a summary of the
20 findings in this study. Anyone seeking a more
21 detailed discussion is referred to the report
22 entitled "Treatment of Waste Water from Tunnel
23 Boring Operations". I would be happy to respond
24 to questions both on this talk and on the previous
25 talk at the end of this presentation.

26 The first slide shows the general
27 areas with which we were concerned in this report.
28 There will be three tunnel headings operating
29 simultaneously; one at the west portal of Rogers
30 Pass tunnel; one at the east portal of the Rogers

(Hollibaugh)

1 Pass tunnel and one at the west portal of the
2 short tunnel. Effluents from the vent shft will
3 also have to be treated. So there will be
4 another treatment facility located near the
5 vent shaft construction site.
6

7 The amount of effluent that will
8 have to be treated depends on a variety of factors
9 and the most important of which is the groundwater
10 flow rate. The amount of water used in the
11 construction tunnel will also be a consideration
12 but it is relatively minor compared to groundwater
13 outflow.

14 We were asked to design a water
15 system to supply water to the drills during tunnel
16 construction. Water requirements for tunnel
17 boring at 80 Imperial Gallons per minute at each
18 tunnel portal and an average of about 30 gallons
19 per minute at the vent shaft. Water for use in
20 drilling at the west portal of the Rogers Pass
21 tunnel would be obtained from the Illecillewaet
22 River; from the Beaver River for the east portal
23 of the Rogers Pass tunnel, and from Connaught
24 Creek for the west portal of the short tunnel.

25 Water for vent shaft construction
26 will be taken from a small stream flowing down slope
27 near the vent shaft site or from the stream flowing
28 down adjacent to the Trans Canada highway at the
29 bottom of the slope. Some of the water to be used
30

(Hollibaugh)

1 vent shaft construction may be recycled from
2 settling ponds or it may also be obtained from
3 groundwater sources in case the streams identified
4 are not adequate.

5 The amount of effluent that
6 will have to be treated from each tunnel portal
7 is the sum of the water which is pumped into
8 the tunnel for use in boring operations plus
9 groundwater which flows out of the formation being
10 penetrated by the tunnel. Groundwater flow rates
11 are difficult to anticipate. The estimate we
12 used is based on general tunneling experience
13 and is in agreement with amounts observed during the
14 construction and subsequent operation of the
15 Connaught Tunnel.

16 Groundwater flow rates average 0.1
17 Imperial Gallon per Minute per lineau foot of
18 tunnel. This is based on a large number of tunnels
19 tunnelled all over the world rather than anything
20 specific to the Rogers Pass area. Multiplying this
21 figure by the length of the Rogers Pass tunnel
22 we obtained an estimate of approximately 2,000
23 Imperial Gallons per Minute from each portal
24 of the tunnel. The short tunnel is, of course,
25 shorter, and so the estimate for that tunnel is
26 about 600 Imperial Gallons per Minute. Flow rates
27 from the vent shaft will have to be controlled
28 because the vent shaft is going to be sunk vertically
29 into the ground and there is a high risk of flooding
30

1 (Hollibaugh)

2 if the flow rates are not controlled. Flow rates
3 in the vent shaft will be restricted to some 80
4 Imperial Gallons per Minute in order for construction
5 to proceed.

6 Depletion of groundwater reservoirs
7 at the Rogers Pass tunnel will result in some
8 decrease in the flow rates during the tunneling
9 operation, particularly at the Rogers Pass tunnel
10 where the boring is expected to take over two years.
11 Because of this factor, we have estimated that
12 flow rates probably will not exceed 1,000 Imperial
13 Gallons per Minute during tunnel construction.
14 Since the short tunnel will be constructed in a
15 much shorter length of time, we have used the original
16 estimate of 600 Imperial Gallons per Minute because
17 we do not feel that there will be sufficient
18 time for the groundwater reservoirs to be depleted.

19 Thus tunnel effluent facilities
20 will have to have maximum capabilities for 1,000
21 Imperial Gallons per Minute from each end of the
22 Rogers Pass tunnel; 600 Imperial Gallons per Minute
23 from the short tunnel, and roughly 80 Imperial
24 Gallons per Minute from the vent shaft. This
25 requires settling ponds with maximum areas of
26 50,000 square feet for each portal of the Rogers
27 Pass tunnel; 30,000 square feet for the west portal
28 of the short tunnel, and 5,000 square feet for the
29 vent shaft. The exact calculations used to
30 derive these numbers are included in the report,

(Hollibaugh)

1 and I will not go through them in detail right
2 here. They depend on the size of particles
3 that one is trying to remove from the effluent.
4

5 As I mentioned above, the water
6 from the tunnel will be comprised of water used in
7 the drilling operations plus groundwater. The
8 tunnel effluent can thus be expected to be
9 contaminated with a number of substances. The
10 major contaminant will be rock dust produced during
11 the blasting operations. In addition, lube oil
12 and grease and hydraulic fluid will drip out of
13 the various machines operating in the tunnels and
14 be mixed in with the groundwater.

15 Residual chemicals from blasting may
16 also contaminate this water. These will be
17 primarily nitrate and nitrite. Residual chemicals
18 from grouting and shotcreting operations, if these
19 are necessary, will also contaminate the water. These
20 will be primarily calcium and hydroxide ion which
21 will result in a high pH.

22 In addition, human waste and
23 trash can be expected to enter the tunnel effluent.
24 Treatment facilities for the short tunnel and the
25 east portal, Rogers Pass tunnel will probably be
26 combined as the two portals are close together.
27 It may be possible to intercept clean groundwater
28 flowing out of the tunnel walls in some areas,
29 particularly if the groundwater is coming out
30 of distinct zones or fissures. This water could
then be discharged directly into a receiving body

1 (Hollibaugh)

2 without having to be treated, thus decreasing the
3 load on the settling ponds or the water treatment
4 facilities.

5 Treatment of tunnel effluent
6 is a two-step process. First the effluent will be
7 passed through oil separators which will be located
8 near the tunnel portals to remove oil and grease.
9 We have designed the oil separator to remove
10 droplets down to 0.15 millimeters in diameter or
11 larger at 4 degrees C. The oil separator will
12 also remove sand and gravel from the effluent.
13 After passing through the oil separator, the tunnel
14 effluent will be piped down to settling ponds.

15 The function of the settling pond is
16 to remove fine sediment not taken out by the oil
17 separator. We have designed the settling ponds
18 to remove silt particles down to .004 millimeters
19 in diameter, 4 microns in diameter. We have also
20 incorporated a baffle and weir system into the
21 settling ponds so that oil not removed by the oil,
22 separators can be prevented from entering the
23 receiving body. Trapped oil can be removed from
24 the surface of the settling pond by a variety of means
25 using standard oil slick control devices.

26 This slide shows a schematic
27 diagram of an oil separator. They are very simple
28 devices. There is an inlet zone where water from
29 the tunnel enters the pond and a baffled outlet zone.
30

1 (Hollibaugh)

2 Oil floats to the surface of the water during its
3 passage along the length of the separator and is
4 prevented from leaving the separator by the
5 baffle and weir system at the end.

6 An oil skimmer of one sort or
7 another is located near the outflow of the pond
8 and removes the accumulated oil and deposits it
9 in a collection tank adjacent to the separator.
10 This tank is emptied periodically and its contents
11 disposed of in an environmentally safe manner.
12 Sediment will also have to be removed from the
13 pond occasionally.

14 We recommend that at least two
15 ponds be constructed, oil separating ponds be
16 constructed at each portal and operated in
17 parallel except when one is shut down during
18 cleaning operations. We feel that the second
19 pond can handle the additional load for short
20 period of time, particularly since we have a back-up
21 system for possible oil escape by the baffle and
22 weir system on the settling pond downstream.

23 The next slide shows a schematic
24 diagram of a settling pond. It is also a very
25 simple device. It is designed so that sinking
26 particles reach the bottom of the pond by the time
27 the water that they are moving with has reached the far
28 end of the pond. Like the oil separator, the inlet is
29 at one end and the outlet is at the other. A
30 baffle and weir system, which is not shown in this

(Hollibaugh)

figure is associated with the outlet zone. Accumulated sediment will be removed from the pond and disposed of or new ponds will be constructed to replace sediment-filled ponds. The bottom of the ponds will be covered with shotcrete or some other sealant in order to prevent water from leaking out of the pond into the surrounding ground.

The ponds should be constructed in modules capable of handling 2,000 (sic) Imperial Gallons per Minute since the maximum flow from the tunnel is not expected to be reached until the tunnelling operation is nearly complete. Pond construction will be scheduled so that a reserve pond is available at all times to meet unexpected increases in flow rates.

The schematic diagram of the complete water supply and water treatment systems for one of the tunnel's portals is shown in this slide. As you can see, there is a supply line taking water in to the tunnel face where it is used in the drilling operations. Effluent leaving the tunnel first passes through the oil separation pond and then enters one or another of the settling pond units where the finer material is removed. The clean effluent is then discharged into an appropriate receiving body.

(Hollibaugh)

We next examined the area around each of the construction sites to look for suitable locations for settling pond construction. The sites we identified are shown in the following slides. Because of various constraints on the use of many of the sites, we met with Parks Canada to discuss the acceptability of each of these sites. The first figure shows sites considered near the east portal of the Roger Pass tunnel and the west portal of the short tunnel. Parks Canada indicated that sites 3, 7 and 8 were acceptable settling pond locations. Three is in the disturbed area which is a borrow pit, I believe for the highway here. Seven and eight are in the two pits on the other side of the Beaver River.

As can be seen on the final design plan shown on C. P. Rail's display, the ponds are to be located at the edge of Site 3. These ponds will handle effluent from both the east portal of the Rogers Pass tunnel and the west portal of the short tunnel. Sites 7 and 8 would only be needed if extremely high flow rates were encountered. Clean effluents from the settling ponds will be discharged downstream into the Beaver River.

Likewise a number of sites were identified near the west portal of the Rogers Pass tunnel. After discussion with Parks Canada Site No. 4, up here, was chosen as a settling pond site.

(Hollibaugh)

This site is located between the existing C. P. Rail mainline and the Trans Canada highway east of the west portal. Effluent from that pond will be discharged into Illecillewaet River.

We identified also two sites near the vent shaft; one adjacent to the Trans Canada highway and one above the access road to the vent shaft construction site. Parks Canada suggested locating the settling pond on the actual vent shaft construction site because neither the two sites we had initially suggested were acceptable. The settling pond location has been moved to the old C. P. rail line adjacent to the vent shaft access road, somewhere down in here. This pond is indicated again on the display in the back of the room. Pond effluent would be discharged into the stream running along the Trans Canada highway here.

Because the key to proper water treatment is anticipating problems and dealing with them before they become severe, we propose a rigorous monitoring program for the pond effluent. This program meets or exceeds the E.P.S. Standards for Government institutions such as the Parks Canada compound at Rogers Pass. The parameters we will be monitoring, the frequency with which they will be monitored, the tolerance limits of these parameters and the action to be taken if the tolerance limits are exceeded are given in the final slide, and for

(Hollibaugh)

1 those of you in the back of the room it is also
2 reproduced in C.P.'s Red Book. Data will be
3 recorded and will be available to the interested
4 public.

5 This completes my presentation
6 and I will now be glad to respond to
7 questions from the Panel or from the audience.

8 THE CHAIRMAN: Panel, do we have
9 any questions concerning this presentation?

10 MR. TENCH: The measures for
11 erosion control seem to relate to a gentle flow
12 or erosion of material from construction slopes.
13 What will happen in the case of a construction
14 mishap or say a slip or a landslide like the
15 one that is existing now? What measures have
16 you got in mind for that sort of situation?

17 MR. HOLLIBAUGH: For cleaning
18 up and preventing it?

19 MR. TENCH: And to prevent the
20 sediment from getting down into beaver areas?

21 MR. HOLLIBAUGH: Well, it would
22 depend on where the slide occurred. In the case
23 of the slide which happened last May, I guess,
24 that was cleaned up right away and was prevented
25 from getting into the beaver pond habitat directly
26 below the slide by the Trans Canada highway.

27 The other areas along the right-of-way,
28 for instance along the avalanche chutes, it will be
29 very difficult to clean that up and, in fact, you
30

1 (Hollibaugh)

2 might cause more damage by trying to clean it up
3 than you would just by leaving it there.

4 Many of those streams right now
5 experience debris flows and mud slides of one
6 sort or another, and that is not say that one
7 should not be worried about that, but in some
8 cases there is not much that can be done.

9 THE CHAIRMAN: I believe we had
10 a question from a member of the audience there.
11 Did somebody want to ask a question?

12 MR. HERRERO: I have been curious
13 in all this erosion control. This is probably
14 not a question that the presentor can answer
15 but one that Parks Canada is going to have to
16 answer if they can. A primary factor that
17 would influence both erosion and also landslide
18 potential once the cuts were made would be forest
19 fire, and I wanted to ask two questions of Parks
20 Canada in this regard.

21 The first is: do they have a policy
22 of complete fire suppression in the immediate
23 area of the construction and up slope from it,
24 and secondly, if they have this policy, do they
25 know enough about the fire potential to know
26 whether they could control say a major lightning
27 strike and a series of fires in a hot year?

28 The questions relates to the potential
29 of a major fire causing a major loss of tree
30 cover, thus the increasing water run-off and water

1 (Hollibaugh)

2 borne erosion and sedimentation.

3 MR. McKNIGHT: I will have to
4 admit, Steve, I am not intimately familiar
5 with the fire control plan for Glacier National
6 Park. Possibly Mr. Gallacher might want to
7 comment on that.

8 I would assume that the fire
9 control would be practiced quite rigorously
10 along the edges of the Trans Canada highway as
11 much for reasons of concern for avalanche
12 control as anything else.

13 What was your other -- the second
14 part of your question?

15 DR. HERRERO: That was it. It is
16 just that fire is such an important factor
17 influencing with erosion and avalanching and I
18 had not heard it mentioned either this afternoon
19 or this evening in terms of the potential for
20 erosion that I wondered if it had been looked at
21 at all.

22 THE CHAIRMAN: Do we have any
23 more Panel questions concerning the presentation?

24 MR. TENCH: It seemed to me that
25 monitoring disturbance of animals by observing
26 the animals seemed to me to be a rather odd way
27 of going around the thing. Is this not sort of
28 a rather negative way to deal with that problem?
29
30

F-1

1 MR. HOLLIBAUGH: Well, in some
2 kinds of disturbance, it is probably going where
3 you can monitor it. For instance, sedimentation,
4 obviously you can measure sediment content in the
5 streams or you can simply observe mud entering the
6 streams or being deposited in the environments.
7 But if, for instance, operation of heavy equipment
8 on the right-of-way adjacent to some of the habitats
9 disturbed maybe the beavers down and they packed up
10 and moved, well that is an impact of one sort or
11 another.

12
13 But the only way that you would
14 know that that was a problem is if they actually
15 packed up and moved, and even at that, you might
16 have a hard time establishing a cause and effect
17 relationship with activity on the right-of-way because
18 they do sometimes just pack up and move.

19 MR. TENCH: But you do not have
20 many options if that is occurring of getting recovery?

21 MR. HOLLIBAUGH: No, that is true.
22 As can be seen by the closest to which the beavers
23 in that Valley come to the highway right now,
24 there is one colony below where the slide was that
25 you can sit there, I watched last spring. It was
26 a pair with four kitts. We sat up on the guardrail
27 watching for a whole afternoon.

28 There is another colony where Soper
29 Creek crosses the ---

30 MR. TENCH: You are using Mr.

F-2

1 Fox's money again.

2 MR. HOLLIBAUGH: Well, we were
3 observing. Anyway, there is another colony where
4 Soper Creek crosses the highway which is being
5 established in what is presently a coniferous
6 forest. They have moved up into that area and
7 are progressing towards the highway, so you know,
8 they are fairly tolerant in some level of disturbance.

9 THE CHAIRMAN: Could I follow up
10 on this question of standards and erosion control.
11 I think tomorrow we are going to hear from David
12 Walker, and I am reading his presentation now.
13 He is suggesting a standard of so many tons per
14 hectare per year. I am wondering whether you
15 can translate that sort of standard into something
16 you can monitor in what you are doing here? How
17 easy is it to get to this sort of standard, tons
18 per hectare per year, which I think is commonly
19 used in conservation circles to parts per million or
20 whatever in the water courses.

21 MR. HOLLIBAUGH: Monitoring
22 concentration of sediment in the water courses
23 and using that to derive amounts of erosion is
24 a very difficult thing to do. The reason for that
25 is that erosion is so much dependent on
26 discontinuous events, rain storms and whatnot like
27 that, that you have to be monitoring continuously
28 in order to get a good record. You have to be there
29 the moment it is happening. What we suggest doing
30

F-3

1 to try to get around that is monitoring some of the
2 downstream habitats. One can look at the area that
3 is influenced by the streams crossing the right-of-
4 way. If you want to you can map the area, go out
5 and measure sediment deposition and then go backwards
6 from a straight volume calculation to determine the
7 amount of sediment that had come down the stream.

8 But actually measuring sediment
9 in the stream, you know, I would suggest it as a
10 backup measure for the direct observations primarily
11 because the case may come up sometime where there
12 is a need to establish cause and effect relationships.

13 THE CHAIRMAN: That also was a
14 suggestion that came up this afternoon of a standard,
15 perhaps ten parts per million above whatever the
16 base line is, but I guess what you are saying is
17 it is pretty darn hard to establish what the base
18 line is. It depends whether there is a storm or
19 what the flow level is?

20 MR. HOLLIBAUGH: Right. The sediment
21 level in the stream before it reaches your right-of-
22 way is going to change abruptly if there is a storm
23 event as well as if there is a severe erosion
24 problem below the right-of-way. Also, you would
25 have to sort of be there on the spot. For instance,
26 we were out there a couple of weeks ago as part of
27 our ongoing monitoring program in these streams,
28 measuring the sediment levels in some of the streams
29 up there, and two avalanche areas had virtually no
30

F-4

1 sediment in the streams. The Beaver River had, I
2 do not know, about 25 parts per million and Stoney
3 Creek had about 40 parts per million. Last fall
4 we measured it again at low flow season. Those
5 levels are much lower.

6 THE CHAIRMAN: Thank you.

7 DR. ROSS: I have just been forced
8 to go back and check the document because I was
9 looking at some of your numbers on your slides, and
10 I see that part of my difficulty may be in someone's
11 inability to convert from C.P. units to metric
12 units because there is simply an inconsistency here.

13 Notwithstanding that, let me proceed.
14 I am slightly worried about the design of your
15 settling ponds and of your oil separating units
16 in terms of their capacity to handle the flows that
17 may be involved. So let me proceed and I will try
18 to make the corrections as I go.

19 This may be just a typo, in any
20 case, you seem to apply first a ground rule, a rule
21 of thumb, a rule of thumb for ground water, I guess,
22 that indicates there will be about 150 litres per
23 second of flow, 2,000 imperial gallons per minute,
24 and then divide it in two because that really does
25 not happen. I am not sure what use a rule of thumb
26 is that is too high by a factor of two, but it seems
27 to me that you may have the potential of having
28 higher flows than the 75 litres per second that
29 you are designing for.
30

F-5

1 I note especially that the
2 B.C. Rail tunnel, which is much shorter than the
3 Rogers Pass tunnel and the Rogers Pass tunnel has
4 expected higher ground water flows, but the B.C.
5 Rail tunnel was giving about 50 litres per second.
6

7 So my first question is what is
8 your ability to deal with a significantly higher
9 flow of water, waste water from the tunnels?

10 MR. HOLLIBAUGH: One would have to
11 increase the number in area of settling ponds.

12 DR. ROSS: My next question then
13 is do you have the space to do that?

14 MR. HOLLIBAUGH: I believe there
15 is more space available on the number 3 area
16 identified, and as I mentioned during the presentation
17 other areas across the Beaver River were discussed
18 at a meeting with Parks Canada. Now, I subsequently
19 learned that these have also been identified for
20 other uses so I am not sure of the status of those
21 areas. But something like that would have to be
22 done.

23 DR. ROSS: Does that give your
24 contractor any further problems if you get much
25 higher flows? I assume that that could cause
26 difficulties as well. Perhaps, Mr. Fox, you could
27 respond to that?

28 MR. FOX: What those flows were,
29 how they were developed, they were developed by
30 the geological consultants, and they made an

F-6

1 assessment of expected ground water flows.

2 Now, how right they are going to
3 be we will find out when we drill the tunnel. It
4 is pretty difficult to say what you are going to
5 hit inside a tunnel. To those were added the
6 water necessary for drilling and so on and so forth.

7 So based on that, the boys have
8 taken that information and they have designed their
9 settling ponds accordingly.

10 Now, what we will probably do so
11 far as the contractor is concerned is that we will
12 not pay him for the expected flows. In other words,
13 he will have to provide for that. Anything above
14 that, we will have to pick up the tab which, of course,
15 will mean more settling ponds and whatever.

16 Now, your other question about
17 if you are unfortunate enough to hit heavy flows
18 which you do not anticipate, it depends on how those
19 flows occur within the tunnel itself and, for instance,
20 you mention Northeast Coal. I happened to see
21 that myself, and looking at it, I felt in my own
22 mind if I had been the owner, I could have done
23 something about it. I would not have let it go
24 into the settling ponds like was done. To me that
25 was a rather ridiculous situation.

26 They probably could not have
27 avoided it the way they went about drilling the
28 tunnel initially, but shortly thereafter they could
29 have done something to save all that rock, et cetera
30

F-7

1 getting into the Wolverine River.

2 Now, that is beyond my jurisdiction
3 but I would have done it differently. What I would
4 have done in a case like they had, I certainly would
5 have put a collector system in there and piped that
6 good, clean water directly into the river which
7 would not hurt anything.

8 DR. ROSS: So there are ways of
9 dealing with excess flows?

10 MR. FOX: Oh yes. Another solution
11 to a problem like that is you always know when you
12 hit that because you generally have a drill ahead of
13 you and that is how they found this. They did not
14 go into it blindly. They knew it was there because
15 the water was coming out at very high pressure.

16 You could have routed that off.
17 That is an expensive way of doing it, but it can
18 be done. It can be routed off. So there are various
19 ways of dealing with that type of thing.

20 MR. HOLLIBAUGH: If I might
21 interject, one other method which I have also
22 discussed in that report that can be used to increase
23 the efficiency of the fixed size of settling ponds
24 that you have available is to turn to the use of --

25 DR. ROSS: Flocculants.

26 MR. HOLLIBAUGH: -- flocculants,
27 right.

28 DR. ROSS: Let me then move on to
29 the oil separation unit. I guess my concern there
30

F-8

1 seemed to arise from the fact, if I read it
2 carefully, and I went back to look at it two or
3 three times, the oil separation unit seems to be
4 designed for only 15 litres per second and divided
5 into two sub-units, but you plan or expect to put
6 75 litres per second through. So to suggest -- if
7 I understand how these things work, since their
8 ability to separate the oil from the water depends
9 on the flow rate, in fact, it is not designed to
10 remove oil at that rate that you claim it is
11 designed for because you are putting five times as
12 much flow through.

13 MR. HOLLIBAUGH: You just put five
14 oil separators if needed.

15 DR. ROSS: No, but you seem to have
16 implied throughout the report, with the one
17 exception of the monitoring program, that you can get
18 by with only sufficient oil separation capacity for
19 15 litres per second and then you will just check
20 and see if it is working by looking for oil films.

21 MR. HOLLIBAUGH: The unit was
22 designed conservatively so that it does have more
23 capacity than what is indicated in there.

24 Also, for instance, as I mentioned,
25 if you switch one off to clean out the accumulated
26 sand and whatnot, then you are of course doubling
27 the flow through the other one if there is only two.

28 DR. ROSS: But in that case you
29 are putting 75 litres per second through something
30

W-9

1 which is technically designed to handle about 7.5
2 or one-tenth of the flow?

3 MR. HOLLIBAUGH: That is right.
4 You have got a settling pond downstream and the
5 system is specifically put that way to catch any
6 of the oil which gets past it.

7 DR. ROSS: You raised the same
8 question again. Do you have the space to add ten
9 times that capacity or five times that capacity for
10 oil separators?

11 MR. HOLLIBAUGH: Yes, those you do
12 because they are quite small units. They are six
13 feet by 25 feet.

14 DR. ROSS: I thought I remember
15 reading somewhere that they were in a place where
16 space was at a premium, but in any case.

17 MR. HOLLIBAUGH: They do not have
18 to be there, they can be moved. They have to be
19 in line somewhere between the river and the settling
20 between the tunnel and the settling pond.

21 MR. TENCH: Is it right that the
22 one at the west portal is a singular tank, Ken, the
23 settling pond there was just one single settling pond?

24 MR. HOLLIBAUGH: No, that would be
25 divided up also.

26 MR. TENCH: Divided?

27 MR. HOLLIBAUGH: Yes.

28 MR. TENCH: I see. So you have got
29 no singulars. What I was getting to when the day
30

F-10

1 comes to clean it out, what happens, but if you have
2 got multiple units, then it is quite obvious.

3 DR. ROSS: You discussed a monitoring
4 program which includes toxicity tests for air
5 fluents and I gather these toxicity tests are done
6 daily; is that correct?

7 MR. HOLLIBAUGH: I recommended that.
8 That is a much higher frequency than is used commonly
9 in these kinds of programs.

10 DR. ROSS: What can you do if you
11 find a problem?

12 MR. HOLLIBAUGH: There are measures
13 indicated on the table that you can do.

14 DR. ROSS: I thought they were a
15 little bit vague in terms of what one does. If there
16 is a problem, you expect it to be from one of those
17 ones which is flagged in here rather than something
18 dissolved in the water?

19 MR. HOLLIBAUGH: Probably. The
20 probable source of the problem would be possibly
21 changes in PH or from grading operations, things
22 like that, or possibly a spill of one sort or
23 another into the water which should not happen because,
24 you know, you separate.

25 DR. ROSS: One of the other things
26 you monitor is the water temperature clearly to
27 prevent freezing. What puzzled me was that your
28 solution to freezing aside from insulating the
29 pipes which presumably you can only do so often boils
30

F-11

1 down to increasing the flow and increasing the
2 flow, as I commented earlier, reduces the effective-
3 ness, and presumably you are going to have freezing
4 in the middle of the winter -- that is a normal
5 expectation -- that is also the lowest sediment
6 content in the rivers and so if you increase the
7 flow and reduce their effectiveness then you will
8 presumably be increasing the suspended load into
9 the rivers at a time when its sediment load is
10 very low in the first place. Is that likely to
11 lead to problems?

12 MR. HOLLIBAUGH: It is possible.
13 However, the temperature problem usually does not
14 occur because your ground water is coming out at
15 a temperature, you know, six to eight degrees
16 commonly, and experience with for instance B.C.
17 Ore Line where they operated at temperatures at
18 35 degrees below zero, they did not have any
19 problem with freezing anywhere in any other ponds.

20 DR. ROSS: I hope I am just going
21 to correct a comment you made during the
22 presentation. You suggested that, and I quote, "one
23 or the other" of the settling pond would be used.
24 Surely they would all be used in parallel?

25 MR. HOLLIBAUGH: Well, unless you
26 have got one turned off to clean it, yes.

27 DR. ROSS: Yes, except for cleaning,
28 but in order to handle that capacity again, it is
29 the same problem, you must flow through all of them?
30

F-12

1 MR. HOLLIBAUGH: Yes. Not in series
2 but in parallel.

3 DR. ROSS: Yes. Lastly, you
4 made a comment I believe in one of the
5 documents dealing with the sediment load in the
6 rivers. This may not be such an important issue
7 any more but I wanted to make sure I understood it.

8 It seems to me that the fish, in
9 particular, and other species in the river are
10 accustomed to a certain seasonal variation in
11 sediment loads, that is about this time of year there
12 are very high sediment loads, high flows and
13 that does not cause any great difficulties for
14 them, but for most of the season, effectively from
15 October, November through to the increased flows
16 in the spring there are very low sediment loads and
17 so it seems to me that certainly by comparison with
18 what occurs to now, it seems to me that looking as
19 you did in some of the analyses at the annual
20 sediment carried is really not a measure of impact
21 on fish or species in the river.

22 MR. HOLLIBAUGH: No, I addressed
23 that in there by looking at the dilution rates and
24 the relative concentration of sediments both in the
25 winter.

26 DR. ROSS: But what does that does
27 that means that all of the problem really arises in
28 the winter at low sediment?

29 MR. HOLLIBAUGH: Yes, that would be
30

F-13

1 the most critical time because during the summers,
2 as you mentioned, the sediment loads are much
3 higher and if using the EPS guidelines for discharges
4 of the kinds of things which will come out of the
5 settling ponds during the summer, it is conceivable
6 that you could discharge the clean, which is to say,
7 oil skimmed absolute directly into the river and
8 still be within the background plus ten.

9 DR. ROSS: No, I agree. Finally,
10 I guess for Mr. Fox, in your red book you indicated
11 that the water from the settling ponds would be
12 recycled for drilling needs. Do you plan to do this
13 anywhere other than at the vent shaft?

14 MR. FOX: No, I do not think we
15 would do it at portals at all.

16 DR. ROSS: I did not think so and
17 I just was not sure when I read that. Thank you.

18 THE CHAIRMAN: Any further questions
19 concerning this presentation? Thank you for your
20 presentation. I would just like to provide an
21 -opportunity for any last questions at this time.

22 I guess I have one to Parks and
23 this goes back to the work camps. It seemed to me
24 in the presentation that you gave tonight that the
25 prime issue for you was one of policy of having work
26 camps in the Park, and I was wondering what the
27 difference was between the situation now with what
28 you are seeing with these work camps and the situation
29 that we were looking at last year in terms of policy
30

14 1 implications of putting a work camp into the Park?
2 We did not hear too much about policy last year and
3 I wondered why this concern suddenly appeared at
4 this time?

5 DR. LEESON: It is a concern that
6 was precipitated by your meeting last year. We
7 had not thought that policy would be as much of
8 an issue amongst the people who commented to us as
9 it was. So it became a point of concern at that point.
10 We asked C.P. to investigate the camps a lot more
11 and answer a lot of questions, and the more we asked
12 and the more was answered, the more concern became
13 until a month ago it was determined, boy, this
14 is a bad deal. We cannot agree to have camps in the
15 Park of the sort that is being talked about.

16 THE CHAIRMAN: Yes, because of the
17 size of the things because there are camps, well,
18 the Trans Canada Highway, for example, there are
19 small work camps, I believe, in the Park. Maybe I
20 am wrong in that one, but there has been in this
21 Park, in Glacier, for example, there have been small
22 camps. It is the size of the thing that is bothering
23 you, is it?

24 DR. LEESON: Well, that certainly
25 compounds the problem, the size of it, yes.

26 THE CHAIRMAN: You are saying it is
27 a reaction to public concern that your hearings
28 expressed to you?

29 DR. LEESON: In part and in part
30

F-15

1 to the reality of all the things that are necessary
2 as we find out more about them.

3 THE CHAIRMAN: Fair enough. One
4 other question, Mr. Fox, for you. We heard a
5 rather crisp presentation from you and what it would
6 cost you to put these work camps outside the Park.
7 I wonder whether you could give us a suitable crisp
8 figure on what it would cost you if you had to stay
9 within the 200 foot right-of-way that you had asked
10 for originally from CTC? If you need time to work
11 on that, that is fine.

12 MR. FOX: Well, I will give you a
13 top of my head figure and I probably will not be
14 too far off. Fifty million dollars.

15 THE CHAIRMAN: Extra. Thank you.

16 DR. ROSS: I wonder if you could --
17 is that just a guesstimate or is that based on ---

18 MR. FOX: That is a guesstimate,
19 Dr. Ross, but I will wage it is not too far off when
20 you are looking at retaining walls at \$100 a square
21 foot.

22 THE CHAIRMAN: The other thing is
23 that I would guess that in some of those areas you
24 would not, under any circumstances, be able to stay
25 within the 200 feet, for example, in the slides areas
26 where your design proposals are for two to one
27 slopes.

28 MR. FOX: Just an absolute
29 impossibility.

THE CHAIRMAN: Are there any further questions at this time from anybody? If not, I would like to thank you for coming along this evening and we will be reconvening tomorrow morning and we will be going into revegetation and reclamation at that time.

Thank you.

---Whereupon the hearing adjourned at 10:00 p.m.
